1.3 Introduction

WCSLIB is a C library, supplied with a full set of Fortran wrappers, that implements the "World Coordinate System" (WCS) standard in FITS (Flexible Image Transport System). It also includes a PGPLOT-based routine, PGSBOX, for drawing general curvilinear coordinate graticules, and also a number of utility programs.

The FITS data format is widely used within the international astronomical community, from the radio to gamma-ray regimes, for data interchange and archive, and also increasingly as an online format. It is described in

- "Definition of The Flexible Image Transport System (FITS)", FITS Standard, Version 3.0, 2008 July 10.

available from the FITS Support Office at http://fits.gsfc.nasa.gov.

The FITS WCS standard is described in

- "Representations of world coordinates in FITS" (Paper I), Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061-1075
- "Representations of celestial coordinates in FITS" (Paper II), Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077-1122
- "Representations of spectral coordinates in FITS" (Paper III), Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L. 2006, A&A, 446, 747
- "Representations of distortions in FITS world coordinate systems", Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22), available from http://www.atnf.csiro.au/people/Mark.↩Calabretta
- "Mapping on the HEALPix Grid" (HPX, Paper V), Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865
- "Representing the 'Butterfly' Projection in FITS: Projection Code XPH" (XPH, Paper VI), Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050
- "Representations of time coordinates in FITS: Time and relative dimension in space" (Paper VII), Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L., Manchester R.N., & Thompson, W.T. 2015, A&A, 574, A36

Reprints of all published papers may be obtained from NASA's Astrophysics Data System (ADS), http↩://adsabs.harvard.edu/. Reprints of Papers I, II (including HPX & XPH), and III are available from http://www.atnf.csiro.au/people/Mark.Calabretta. This site also includes errata and supplementary material for Papers I, II and III.

Additional information on all aspects of FITS and its various software implementations may be found at the FITS Support Office http://fits.gsfc.nasa.gov.

1.4 FITS-WCS and related software

Several implementations of the FITS WCS standards are available:

- The WCSLIB software distribution (i.e. this library) may be obtained from http://www.atnf.↩csiro.au/people/Mark.Calabretta/WCS/. The remainder of this manual describes its use.

  WCSLIB is included in the Astrophysics Source Code Library (**ASCL** https://ascl.net) as record ascl:1108.003 (https://ascl.net/1108.003), and in the Astrophysics Data System (**ADS** https://ui.adsabs.harvard.edu) with bibcode 2011ascl.soft08003C (https://ui.↩adsabs.harvard.edu/abs/2011ascl.soft08003C).

- **wcstools**, developed by Jessica Mink, may be obtained from http://tdc-www.harvard.↩edu/software/wcstools/.

  ASCL: https://ascl.net/1109.015
  ADS: https://ui.adsabs.harvard.edu/abs/2011ascl.soft09015M

- **AST**, developed by David Berry within the U.K. Starlink project, http://www.starlink.↩ac.uk/ast/ and now supported by JAC, Hawaii http://starlink.jach.hawaii.↩edu/starlink/. A useful utility for experimenting with FITS WCS descriptions (similar to *wcsgrid*) is also provided; go to the above site and then look at the section entitled "FITS-WCS Plotting Demo".

  ASCL: https://ascl.net/1404.016
  ADS: https://ui.adsabs.harvard.edu/abs/2014ascl.soft04016B

- **SolarSoft**, http://sohowww.nascom.nasa.gov/solarsoft/, primarily an IDL-based system for analysis of Solar physics data, contains a module written by Bill Thompson oriented towards Solar coordinate systems, including spectral, http://sohowww.nascom.nasa.↩gov/solarsoft/gen/idl/wcs/.

  ASCL: https://ascl.net/1208.013
  ADS: https://ui.adsabs.harvard.edu/abs/2012ascl.soft08013F

- The IDL Astronomy Library, http://idlastro.gsfc.nasa.gov/, contains an independent implementation of FITS-WCS in IDL by Rick Balsano, Wayne Landsman and others. See http↩://idlastro.gsfc.nasa.gov/contents.html#C5.

Python wrappers to WCSLIB are provided by

- The **Kapteyn Package** http://www.astro.rug.nl/software/kapteyn/ by Hans Terlouw and Martin Vogelaar.

  ASCL: https://ascl.net/1611.010
  ADS: https://ui.adsabs.harvard.edu/abs/2016ascl.soft11010T

- **pywcs**, http://stsdas.stsci.edu/astrolib/pywcs/ by Michael Droettboom, which is distributed within Astropy, https://www.astropy.org.

  ASCL (Astropy): https://ascl.net/1304.002
  ADS (Astropy): https://ui.adsabs.harvard.edu/abs/2013ascl.soft04002G

Java is supported via

- CADC/CCDA Java Native Interface (JNI) bindings to WCSLIB 4.2 http://www.cadc-ccda.↩hia-iha.nrc-cnrc.gc.ca/cadc/source/ by Patrick Dowler.

and Javascript by

- **wcsjs**, https://github.com/astrojs/wcsjs, a port created by Amit Kapadia using Emscripten, an LLVM to Javascript compiler. wcsjs provides a code base for running WCSLIB on web browsers.

Julia wrappers (https://en.wikipedia.org/wiki/Julia_(programming_language)) are provided by

- **WCS.jl**, https://github.com/JuliaAstro/WCS.jl, a component of Julia Astro, https↩://github.com/JuliaAstro.

An interface for the R programming language (https://en.wikipedia.org/wiki/R_(programming_language)) is available at

- **Rwcs**, https://github.com/asgr/Rwcs/ by Aaron Robotham.

Recommended WCS-aware FITS image viewers:

- Bill Joye's **DS9**, http://hea-www.harvard.edu/RD/ds9/, and
  ASCL: https://ascl.net/0003.002
  ADS: https://ui.adsabs.harvard.edu/abs/2000ascl.soft03002S
- **Fv** by Pan Chai, http://heasarc.gsfc.nasa.gov/ftools/fv/.
  ASCL: https://ascl.net/1205.005
  ADS: https://ui.adsabs.harvard.edu/abs/2012ascl.soft05005P

both handle 2-D images.

Currently (2013/01/29) I know of no image viewers that handle 1-D spectra properly nor multi-dimensional data, not even multi-dimensional data with only two non-degenerate image axes (please inform me if you know otherwise).

Pre-built WCSLIB packages are available, generally a little behind the main release (this list will probably be stale by the time you read it, best do a web search):

- archlinux (tgz), https://www.archlinux.org/packages/extra/i686/wcslib.
- Debian (deb), http://packages.debian.org/search?keywords=wcslib.
- Fedora (RPM), https://admin.fedoraproject.org/pkgdb/package/wcslib.
- Fresh Ports (RPM), http://www.freshports.org/astro/wcslib.
- Gentoo, http://packages.gentoo.org/package/sci-astronomy/wcslib.
- Homebrew (MacOSX), https://github.com/Homebrew/homebrew-science.
- RPM (general) http://rpmfind.net/linux/rpm2html/search.php?query=wcslib, http://www.rpmseek.com/rpm-pl/wcslib.html.
- Ubuntu (deb), https://launchpad.net/ubuntu/+source/wcslib.

Bill Pence's general FITS IO library, **CFITSIO** is available from http://heasarc.gsfc.nasa.gov/fitsio/. It is used optionally by some of the high-level WCSLIB test programs and is required by two of the utility programs.

ASCL: https://ascl.net/1010.001
ADS: https://ui.adsabs.harvard.edu/abs/2010ascl.soft10001P

PGPLOT, Tim Pearson's Fortran plotting package on which PGSBOX is based, also used by some of the WCSLIB self-test suite and a utility program, is available from http://astro.caltech.edu/~tjp/pgplot/.

ASCL: https://ascl.net/1103.002
ADS: https://ui.adsabs.harvard.edu/abs/2011ascl.soft03002P

1.5 Overview of WCSLIB

WCSLIB is documented in the prologues of its header files which provide a detailed description of the purpose of each function and its interface (this material is, of course, used to generate the doxygen manual). Here we explain how the library as a whole is structured. We will normally refer to WCSLIB 'routines', meaning C functions or Fortran 'subroutines', though the latter are actually wrappers implemented in C.

WCSLIB is layered software, each layer depends only on those beneath; understanding WCSLIB first means understanding its stratigraphy. There are essentially three levels, though some intermediate levels exist within these:

- The **top layer** consists of routines that provide the connection between FITS files and the high-level WCSLIB data structures, the main function being to parse a FITS header, extract WCS information, and copy it into a wcsprm struct. The lexical parsers among these are implemented as Flex descriptions (source files with .l suffix) and the C code generated from these by Flex is included in the source distribution.
  - wcshdr.h,c – Routines for constructing wcsprm data structures from information in a FITS header and conversely for writing a wcsprm struct out as a FITS header.
  - wcspih.l – Flex implementation of wcspih(), a lexical parser for WCS "keyrecords" in an image header. A ***keyrecord*** (formerly called "card image") consists of a ***keyword***, its value - the ***keyvalue*** - and an optional comment, the ***keycomment***.
  - wcsbth.l – Flex implementation of wcsbth() which parses binary table image array and pixel list headers in addition to image array headers.
  - getwcstab.h,c – Implementation of a -TAB binary table reader in CFITSIO.

  A generic FITS header parser is also provided to handle non-WCS keyrecords that are ignored by wcspih():
  - fitshdr.h,l – Generic FITS header parser (not WCS-specific).

  The philosophy adopted for dealing with non-standard WCS usage is to translate it at this level so that the middle- and low-level routines need only deal with standard constructs:
  - wcsfix.h,c – Translator for non-standard FITS WCS constructs (uses wcsutrne()).
  - wcsutrn.l – Lexical translator for non-standard units specifications.

  As a concrete example, within this layer the `CTYPEia` keyvalues would be extracted from a FITS header and copied into the *ctype*[] array within a wcsprm struct. None of the header keyrecords are interpreted.
- The **middle layer** analyses the WCS information obtained from the FITS header by the top-level routines, identifying the separate steps of the WCS algorithm chain for each of the coordinate axes in the image. It constructs the various data structures on which the low-level routines are based and invokes them in the correct sequence. Thus the wcsprm struct is essentially the glue that binds together the low-level routines into a complete coordinate description.
  - wcs.h,c – Driver routines for the low-level routines.
  - wcsunits.h,c – Unit conversions (uses wcsulexe()).
  - wcsulex.l – Lexical parser for units specifications.

  To continue the above example, within this layer the *ctype*[] keyvalues in a wcsprm struct are analysed to determine the nature of the coordinate axes in the image.
- Applications programmers who use the top- and middle-level routines generally need know nothing about the **low-level routines**. These are essentially mathematical in nature and largely independent of FITS itself. The mathematical formulae and algorithms cited in the WCS Papers, for example the spherical projection equations of Paper II and the lookup-table methods of Paper III, are implemented by the routines in this layer, some of which serve to aggregate others:

  - cel.h,c – Celestial coordinate transformations, combines prj.h,c and sph.h,c.
  - spc.h,c – Spectral coordinate transformations, combines transformations from spx.h,c.

  The remainder of the routines in this level are independent of everything other than the grass-roots mathematical functions:

  - lin.h,c – Linear transformation matrix.
  - dis.h,c – Distortion functions.
  - log.h,c – Logarithmic coordinates.
  - prj.h,c – Spherical projection equations.
  - sph.h,c – Spherical coordinate transformations.
  - spx.h,c – Basic spectral transformations.
  - tab.h,c – Coordinate lookup tables.

  As the routines within this layer are quite generic, some, principally the implementation of the spherical projection equations, have been used in other packages (AST, wcstools) that provide their own implementations of the functionality of the top and middle-level routines.

- At the **grass-roots level** there are a number of mathematical and utility routines.

  When dealing with celestial coordinate systems it is often desirable to use an angular measure that provides an exact representation of the latitude of the north or south pole. The WCSLIB routines use the following trigonometric functions that take or return angles in degrees:

  - cosd(), sind(), sincosd(), tand(), acosd(), asind(), atand(), atan2d()

  These "trigd" routines are expected to handle angles that are a multiple of 90° returning an exact result. Some C implementations provide these as part of a system library and in such cases it may (or may not!) be preferable to use them. wcstrig.c provides wrappers on the standard trig functions based on radian measure, adding tests for multiples of 90°.

  However, wcstrig.h also provides the choice of using preprocessor macro implementations of the trigd functions that don't test for multiples of 90° (compile with `-DWCSTRIG_MACRO`). These are typically 20% faster but may lead to problems near the poles.

  - wcsmath.h – Defines mathematical and other constants.
  - wcstrig.h,c – Various implementations of trigd functions.
  - wcsutil.h,c – Simple utility functions for string manipulation, etc. used by WCSLIB.

Complementary to the C library, a set of wrappers are provided that allow all WCSLIB C functions to be called by Fortran programs, see below.

Plotting of coordinate graticules is one of the more important requirements of a world coordinate system. WCSLIB provides a PGPLOT-based subroutine, PGSBOX (Fortran), which handles general curvilinear coordinates via a user-supplied function - `PGWCSL` provides the interface to WCSLIB. A C wrapper, *cpgsbox()*, is also provided, see below.

Several utility programs are distributed with WCSLIB:

- *wcsgrid* extracts the WCS keywords for an image from the specified FITS file and uses *cpgsbox()* to plot a 2-D coordinate graticule for it. It requires WCSLIB, PGSBOX and CFITSIO.
- *wcsware* extracts the WCS keywords for an image from the specified FITS file and constructs wcsprm structs for each coordinate representation found. The structs may then be printed or used to transform pixel coordinates to world coordinates. It requires WCSLIB and CFITSIO.

- *HPXcvt* reorganises HEALPix data into a 2-D FITS image with HPX coordinate system. The input data may be stored in a FITS file as a primary image or image extension, or as a binary table extension. Both NESTED and RING pixel indices are supported. It uses CFITSIO.
- *fitshdr* lists headers from a FITS file specified on the command line, or else on stdin, printing them as 80-character keyrecords without trailing blanks. It is independent of WCSLIB.

1.6 WCSLIB data structures

The WCSLIB routines are based on data structures specific to them: wcsprm for the wcs.h,c routines, celprm for cel.h,c, and likewise spcprm, linprm, prjprm, tabprm, and disprm, with struct definitions contained in the corresponding header files: wcs.h, cel.h, etc. The structs store the parameters that define a coordinate transformation and also intermediate values derived from those parameters. As a high-level object, the wcsprm struct contains linprm, tabprm, spcprm, and celprm structs, and in turn the linprm struct contains disprm structs, and the celprm struct contains a prjprm struct. Hence the wcsprm struct contains everything needed for a complete coordinate description.

Applications programmers who use the top- and middle-level routines generally only need to pass wcsprm structs from one routine that fills them to another that uses them. However, since these structs are fundamental to WCSLIB it is worthwhile knowing something about the way they work.

Three basic operations apply to all WCSLIB structs:

- Initialize. Each struct has a specific initialization routine, e.g. wcsinit(), celini(), spcini(), etc. These allocate memory (if required) and set all struct members to default values.
- Fill in the required values. Each struct has members whose values must be provided. For example, for wcsprm these values correspond to FITS WCS header keyvalues as are provided by the top-level header parsing routine, wcspih().
- Compute intermediate values. Specific setup routines, e.g. wcsset(), celset(), spcset(), etc., compute intermediate values from the values provided. In particular, wcsset() analyses the FITS WCS keyvalues provided, fills the required values in the lower-level structs contained in wcsprm, and invokes the setup routine for each of them.

Each struct contains a *flag* member that records its setup state. This is cleared by the initialization routine and checked by the routines that use the struct; they will invoke the setup routine automatically if necessary, hence it need not be invoked specifically by the application programmer. However, if any of the required values in a struct are changed then either the setup routine must be invoked on it, or else the *flag* must be zeroed to signal that the struct needs to be reset.

The initialization routine may be invoked repeatedly on a struct if it is desired to reuse it. However, the *flag* member of structs that contain allocated memory (wcsprm, linprm, tabprm, and disprm) must be set to -1 before the first initialization to initialize memory management, but not subsequently or else memory leaks will result.

Each struct has one or more service routines: to do deep copies from one to another, to print its contents, and to free allocated memory. Refer to the header files for a detailed description.

1.7 Memory management

The initialization routines for certain of the WCSLIB data structures allocate memory for some of their members:

- wcsinit() optionally allocates memory for the *crpix*, *pc*, *cdelt*, *crval*, *cunit*, *ctype*, *pv*, *ps*, *cd*, *crota*, *colax*, *cname*, *crder*, and *csyer* arrays in the wcsprm struct (using lininit() for certain of these). Note that wcsinit() does not allocate memory for the *tab* array - refer to the usage notes for wcstab() in wcshdr.h. If the *pc* matrix is not unity, wcsset() (via linset()) also allocates memory for the *piximg* and *imgpix* arrays.
- lininit(): optionally allocates memory for the *crpix*, *pc*, and *cdelt* arrays in the linprm struct. If the *pc* matrix is not unity, linset() also allocates memory for the *piximg* and *imgpix* arrays. Typically these would be used by wcsinit() and wcsset().
- tabini(): optionally allocates memory for the *K*, *map*, *crval*, *index*, and *coord* arrays (including the arrays referenced by *index*[]) in the tabprm struct. tabmem() takes control of any of these arrays that may have been allocated by the user, specifically in that tabfree() will then free it. tabset() also allocates memory for the *sense*, *p0*, *delta* and *extrema* arrays.
- disinit(): optionally allocates memory for the *dtype*, *dp*, and *maxdis* arrays. disset() also allocates memory for a number of arrays that hold distortion parmeters and intermediate values: *axmap*, *Nhat*, *offset*, *scale*, *iparm*, and *dparm*, and also several private work arrays: *disp2x*, *disx2p*, and *tmpmem*.

The caller may load data into these arrays but must not modify the struct members (i.e. the pointers) themselves or else memory leaks will result.

wcsinit() maintains a record of memory it has allocated and this is used by wcsfree() which wcsinit() uses to free any memory that it may have allocated on a previous invokation. Thus it is not necessary for the caller to invoke wcsfree() separately if wcsinit() is invoked repeatedly on the same wcsprm struct. Likewise, wcsset() deallocates memory that it may have allocated on a previous invokation. The same comments apply to lininit(), linfree(), and linset(), to tabini(), tabfree(), and tabset(), and to disinit(), disfree() and disset().

A memory leak will result if a wcsprm, linprm, tabprm, or disprm struct goes out of scope before the memory has been *free'd*, either by the relevant routine, wcsfree(), linfree(), tabfree(), or disfree() or otherwise. Likewise, if one of these structs itself has been *malloc'd* and the allocated memory is not *free'd* when the memory for the struct is *free'd*. A leak may also arise if the caller interferes with the array pointers in the "private" part of these structs.

Beware of making a shallow copy of a wcsprm, linprm, tabprm, or disprm struct by assignment; any changes made to allocated memory in one would be reflected in the other, and if the memory allocated for one was *free'd* the other would reference unallocated memory. Use the relevant routine instead to make a deep copy: wcssub(), lincpy(), tabcpy(), or discpy().

1.8 Diagnostic output

All WCSLIB functions return a status value, each of which is associated with a fixed error message which may be used for diagnostic output. For example

```
int status;
struct wcsprm wcs;

...

if ((status = wcsset(&wcs)) {
  fprintf(stderr, "ERROR %d from wcsset(): %s.\n", status, wcs_errmsg[status]);
  return status;
}
```

This might produce output like

```
ERROR 5 from wcsset(): Invalid parameter value.
```

The error messages are provided as global variables with names of the form *cel_errmsg*, *prj_errmsg*, etc. by including the relevant header file.

As of version 4.8, courtesy of Michael Droettboom (pywcs), WCSLIB has a second error messaging system which provides more detailed information about errors, including the function, source file, and line number where the error occurred. For example,

```
struct wcsprm wcs;

/* Enable wcserr and send messages to stderr. */
wcserr_enable(1);
wcsprintf_set(stderr);

...

if (wcsset(&wcs) {
  wcsperr(&wcs);
  return wcs.err->status;
}
```

In this example, if an error was generated in one of the prjset() functions, wcsperr() would print an error traceback starting with wcsset(), then celset(), and finally the particular projection-setting function that generated the error. For each of them it would print the status return value, function name, source file, line number, and an error message which may be more specific and informative than the general error messages reported in the first example. For example, in response to a deliberately generated error, the `twcs` test program, which tests wcserr among other things, produces a traceback similar to this:

```
ERROR 5 in wcsset() at line 1564 of file wcs.c:
  Invalid parameter value.
ERROR 2 in celset() at line 196 of file cel.c:
  Invalid projection parameters.
ERROR 2 in bonset() at line 5727 of file prj.c:
  Invalid parameters for Bonne's projection.
```

Each of the structs in WCSLIB includes a pointer, called *err*, to a wcserr struct. When an error occurs, a struct is allocated and error information stored in it. The wcserr pointers and the memory allocated for them are managed by the routines that manage the various structs such as wcsinit() and wcsfree().

wcserr messaging is an opt-in system enabled via wcserr_enable(), as in the example above. If enabled, when an error occurs it is the user's responsibility to free the memory allocated for the error message using wcsfree(), celfree(), prjfree(), etc. Failure to do so before the struct goes out of scope will result in memory leaks (if execution continues beyond the error).

1.9 Vector API

WCSLIB's API is vector-oriented. At the least, this allows the function call overhead to be amortised by spreading it over multiple coordinate transformations. However, vector computations may provide an opportunity for caching intermediate calculations and this can produce much more significant efficiencies. For example, many of the spherical projection equations are partially or fully separable in the mathematical sense, i.e. $(x, y) = f(\phi)g(\theta)$, so if θ was invariant for a set of coordinate transformations then $g(\theta)$ would only need to be computed once. Depending on the circumstances, this may well lead to speedups of a factor of two or more.

WCSLIB has two different categories of vector API:

- Certain steps in the WCS algorithm chain operate on coordinate vectors as a whole rather than particular elements of it. For example, the linear transformation takes one or more pixel coordinate vectors, multiples by the transformation matrix, and returns whole intermediate world coordinate vectors.
  The routines that implement these steps, wcsp2s(), wcss2p(), linp2x(), linx2p(), tabx2s(), tabs2x(), disp2x() and disx2p() accept and return two-dimensional arrays, i.e. a number of coordinate vectors. Because WCSLIB permits these arrays to contain unused elements, three parameters are needed to describe them:

  - *naxis:* the number of coordinate elements, as per the FITS `NAXIS` or `WCSAXES` keyvalues,
  - *ncoord:* the number of coordinate vectors,
  - *nelem:* the total number of elements in each vector, unused as well as used. Clearly, *nelem* must equal or exceed *naxis*. (Note that when *ncoord* is unity, *nelem* is irrelevant and so is ignored. It may be set to 0.)

  ncoord and *nelem* are specified as function arguments while *naxis* is provided as a member of the wcsprm (or linprm or disprm) struct.
  For example, wcss2p() accepts an array of world coordinate vectors, *world[ncoord][nelem]*. In the following example, *naxis* = 4, *ncoord* = 5, and *nelem* = 7:

```
s1  x1  y1  t1  u   u   u
s2  x2  y2  t2  u   u   u
s3  x3  y3  t3  u   u   u
s4  x4  y4  t4  u   u   u
s5  x5  y5  t5  u   u   u
```

  where *u* indicates unused array elements, and the array is laid out in memory as

```
s1  x1  y1  t1  u   u   u   s2  x2  y2  ...
```

  Note that the *stat[]* vector returned by routines in this category is of length *ncoord*, as are the intermediate *phi[]* and *theta[]* vectors returned by wcsp2s() and wcss2p().
  Note also that the function prototypes for routines in this category have to declare these two-dimensional arrays as one-dimensional vectors in order to avoid warnings from the C compiler about declaration of "incomplete types". This was considered preferable to declaring them as simple pointers-to-double which gives no indication that storage is associated with them.

- Other steps in the WCS algorithm chain typically operate only on a part of the coordinate vector. For example, a spectral transformation operates on only one element of an intermediate world coordinate that may also contain celestial coordinate elements. In the above example, spcx2s() might operate only on the *s* (spectral) coordinate elements.
  Routines like spcx2s() and celx2s() that implement these steps accept and return one-dimensional vectors in which the coordinate element of interest is specified via a starting address, a length, and a stride. To continue the previous example, the starting address for the spectral elements is *s1*, the length is 5, and the stride is 7.

1.9.1 Vector lengths

Routines such as spcx2s() and celx2s() accept and return either one coordinate vector, or a pair of coordinate vectors (one-dimensional C arrays). As explained above, the coordinate elements of interest are usually embedded in a two-dimensional array and must be selected by specifying a starting point, length and stride through the array. For routines such as spcx2s() that operate on a single element of each coordinate vector these parameters have a straightforward interpretation.

However, for routines such as celx2s() that operate on a pair of elements in each coordinate vector, WCSLIB allows these parameters to be specified independently for each input vector, thereby providing a much more general interpretation than strictly needed to traverse an array.

This is best described by illustration. The following diagram describes the situation for cels2x(), as a specific example, with *nlng = 5*, and *nlat = 3:*

```
            lng[0]    lng[1]    lng[2]    lng[3]    lng[4]
            ------    ------    ------    ------    ------
lat[0]   |  x,y[0]    x,y[1]    x,y[2]    x,y[3]    x,y[4]
lat[1]   |  x,y[5]    x,y[6]    x,y[7]    x,y[8]    x,y[9]
lat[2]   |  x,y[10]   x,y[11]   x,y[12]   x,y[13]   x,y[14]
```

In this case, while only 5 longitude elements and 3 latitude elements are specified, the world-to-pixel routine would calculate *nlng* $*$ *nlat = 15 (x,y)* coordinate pairs. It is the responsibility of the caller to ensure that sufficient space has been allocated in ***all*** of the output arrays, in this case *phi[]*, *theta[]*, *x[]*, *y[]* and *stat[]*.

Vector computation will often be required where neither *lng* nor *lat* is constant. This is accomplished by setting *nlat* = 0 which is interpreted to mean *nlat = nlng* but only the matrix diagonal is to be computed. Thus, for *nlng = 3* and *nlat = 0* only three *(x,y)* coordinate pairs are computed:

```
            lng[0]    lng[1]    lng[2]
            ------    ------    ------
lat[0]   |  x,y[0]
lat[1]   |            x,y[1]
lat[2]   |                      x,y[2]
```

Note how this differs from *nlng = 3, nlat = 1*:

```
            lng[0]    lng[1]    lng[2]
            ------    ------    ------
lat[0]   |  x,y[0]    x,y[1]    x,y[2]
```

The situation for celx2s() is similar; the *x*-coordinate (like *lng*) varies fastest.

Similar comments can be made for all routines that accept arguments specifying vector length(s) and stride(s). (tabx2s() and tabs2x() do not fall into this category because the `-TAB` algorithm is fully *N*-dimensional so there is no way to know in advance how many coordinate elements may be involved.)

The reason that WCSLIB allows this generality is related to the aforementioned opportunities that vector computations may provide for caching intermediate calculations and the significant efficiencies that can result. The high-level routines, wcsp2s() and wcss2p(), look for opportunities to collapse a set of coordinate transformations where one of the coordinate elements is invariant, and the low-level routines take advantage of such to cache intermediate calculations.

1.9.2 Vector strides

As explained above, the vector stride arguments allow the caller to specify that successive elements of a vector are not contiguous in memory. This applies equally to vectors given to, or returned from a function.

As a further example consider the following two arrangements in memory of the elements of four *(x,y)* coordinate pairs together with an *s* coordinate element (e.g. spectral):

- *x1 x2 x3 x4 y1 y2 y3 y4 s1 s2 s3 s4*
  the address of *x[]* is *x1*, its stride is 1, and length 4,
  the address of *y[]* is *y1*, its stride is 1, and length 4,
  the address of *s[]* is *s1*, its stride is 1, and length 4.
- *x1 y1 s1 x2 y2 s2 x3 y3 s3 x4 y4 s4*
  the address of *x[]* is *x1*, its stride is 3, and length 4,
  the address of *y[]* is *y1*, its stride is 3, and length 4,
  the address of *s[]* is *s1*, its stride is 3, and length 4.

For routines such as cels2x(), each of the pair of input vectors is assumed to have the same stride. Each of the output vectors also has the same stride, though it may differ from the input stride. For example, for cels2x() the input *lng[]* and *lat[]* vectors each have vector stride *sll*, while the *x[]* and *y[]* output vectors have stride *sxy*. However, the intermediate *phi[]* and *theta[]* arrays each have unit stride, as does the *stat[]* vector.

If the vector length is 1 then the stride is irrelevant and so ignored. It may be set to 0.

1.10 Thread-safety

Thanks to feedback and patches provided by Rodrigo Tobar Carrizo, as of release 5.18, WCSLIB is now completely thread-safe, with only a couple of minor provisos.

In particular, a number of new routines were introduced to preclude altering the global variables NPVMAX, NPSMAX, and NDPMAX, which determine how much memory to allocate for storing PVi_ma, PSi_ma, DPja, and DQia keyvalues: wcsinit(), lininit(), lindist(), and disinit(). Specifically, these new routines are now used by various WCSLIB routines, such as the header parsers, which previously temporarily altered the global variables, thus posing a thread hazard.

In addition, the Flex scanners were made reentrant and consequently should now be thread-safe. This was achieved by rewriting them as thin wrappers (with the same API) over scanners that were modified (with changed API), as required to use Flex's "reentrant" option.

For complete thread-safety, please observe the following provisos:

- The low-level routines wcsnpv(), wcsnps(), and disndp() are not thread-safe, but they are not used within WCSLIB itself other than to get (not set) the values of the global variables NPVMAX, NPSMAX, and NDPMAX.

  wcsinit() and disinit() only do so to get default values if the relevant parameters are not provided as function arguments. Note that wcsini() invokes wcsinit() with defaults which cause this behavior, as does disini() invoking disinit().

  The preset values of NPVMAX(=64), NPSMAX(=8), and NDPMAX(=256) are large enough to cover most practical cases. However, it may be desirable to tailor them to avoid allocating memory that remains unused. If so, and thread-safety is an issue, then use wcsinit() and disinit() instead with the relevant values specified. This is what WCSLIB routines, such as the header parsers wcspih() and wcsbth(), do to avoid wasting memory.

- wcserr_enable() sets a static variable and so is not thread-safe. However, the error reporting facility is not intended to be used dynamically. If detailed error messages are required, enable wcserr when execution starts and don't change it.

Note that diagnostic routines that print the contents of the various structs, namely celprt(), disprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcsperr() use printf() which is thread-safe by the POSIX requirement on `stdio`. However, this is only at the function level. Where multiple threads invoke these routines simultaneously their output is likely to be interleaved.

1.11 Limits

While the FITS WCS standard imposes a limit of 99 on the number of image coordinate axes, WCSLIB has a limit of 32 on the number it can handle – enforced by wcsset(), though allowed by wcsinit(). This arises in wcsp2s() and wcss2p() from the use of the *stat[]* vector as a bit mask to indicate invalid pixel or world coordinate elements.

In the unlikely event that it ever becomes necessary to handle more than 32 axes, it would be a simple matter to modify the *stat[]* bit mask so that bit 32 applies to all axes beyond 31. However, it was not considered worth introducing the various tests required just for the sake of pandering to unrealistic possibilities.

In addition, wcssub() has a hard-coded limit of 32 coordinate elements (matching the *stat[]* bit mask), and likewise for tabs2p() (via a static helper function, tabvox()). While it would be a simple matter to generalise this by allocating memory from the heap, since tabvox() calls itself recursively and needs to be as fast as possible, again it was not considered worth pandering to unrealistic possibilities.

1.12 Example code, testing and verification

WCSLIB has an extensive test suite that also provides programming templates as well as demonstrations. Test programs, with names that indicate the main WCSLIB routine under test, reside in ./{C,Fortran}/test and each contains a brief description of its purpose.

The high- and middle-level test programs are more instructive for applications programming, while the low-level tests are important for verifying the integrity of the mathematical routines.

- High level:
  twcstab provides an example of high-level applications programming using WCSLIB and CFITSIO. It constructs an input FITS test file, specifically for testing TAB coordinates, partly using `wcstab.keyrec`, and then extracts the coordinate description from it following the steps outlined in wcshdr.h.

  tpih1 and *tpih2* verify wcspih(). The first prints the contents of the structs returned by wcspih() using wcsprt() and the second uses *cpgsbox()* to draw coordinate graticules. Input for these comes from a FITS WCS test header implemented as a list of keyrecords, `wcs.keyrec`, one keyrecord per line, together with a program, *tofits*, that compiles these into a valid FITS file.

  tbth1 tests wcsbth() by reading a test header and printing the resulting wcsprm structs. In the process it also tests wcsfix().

  tfitshdr also uses `wcs.keyrec` to test the generic FITS header parsing routine.

  twcsfix sets up a wcsprm struct containing various non-standard constructs and then invokes wcsfix() to translate them all to standard usage.

  twcslint tests the syntax checker for FITS WCS keyrecords (wcsware -l) on a specially constructed header riddled with invalid entries.

  tdis3 uses wcsware to test the handling of different types of distortion functions encoded in a set of test FITS headers.

- Middle level:
  twcs tests closure of wcss2p() and wcsp2s() for a number of selected projections. *twcsmix* verifies wcsmix() on the 1° grid of celestial longitude and latitude for a number of selected projections. It plots a test grid for each projection and indicates the location of successful and failed solutions. *tdis2* and *twcssub* test the extraction of a coordinate description for a subimage from a wcsprm struct by wcssub().

  tunits tests wcsutrne(), wcsunitse() and wcsulexe(), the units specification translator, converter and parser, either interactively or using a list of units specifications contained in units_test.

  twcscompare tests particular aspects of the comparison routine, wcscompare().

- Low level:
  tdis1, *tlin*, *tlog*, *tprj1*, *tspc*, *tsph*, *tspx*, and ttab1 test "closure" of the respective routines. Closure tests apply the forward and reverse transformations in sequence and compare the result with the original value. Ideally, the result should agree exactly, but because of floating point rounding errors there is usually a small discrepancy so it is only required to agree within a "closure tolerance".

  tprj1 tests for closure separately for longitude and latitude except at the poles where it only tests for closure in latitude. Note that closure in longitude does not deal with angular displacements on the sky. This is appropriate for many projections such as the cylindricals where circumpolar parallels are projected at the same length as the equator. On the other hand, *tsph* does test for closure in angular displacement.

  The tolerance for reporting closure discrepancies is set at 10^{-10} degree for most projections; this is slightly less than 3 microarcsec. The worst case closure figure is reported for each projection and this is usually better than the reporting tolerance by several orders of magnitude. *tprj1* and *tsph* test closure at all

points on the 1° grid of native longitude and latitude and to within 5° of any latitude of divergence for those projections that cannot represent the full sphere. Closure is also tested at a sequence of points close to the reference point (*tprj1*) or pole (*tsph*).

Closure has been verified at all test points for SUN workstations. However, non-closure may be observed for other machines near native latitude -90° for the zenithal, cylindrical and conic equal area projections (**ZEA**, **CEA** and **COE**), and near divergent latitudes of projections such as the azimuthal perspective and stereographic projections (**AZP** and **STG**). Rounding errors may also carry points between faces of the quad-cube projections (**CSC**, **QSC**, and **TSC**). Although such excursions may produce long lists of non-closure points, this is not necessarily indicative of a fundamental problem.

Note that the inverse of the COBE quad-qube projection (**CSC**) is a polynomial approximation and its closure tolerance is intrinsically poor.

Although tests for closure help to verify the internal consistency of the routines they do not verify them in an absolute sense. This is partly addressed by *tcel1*, *tcel2*, *tprj2*, *ttab2* and *ttab3* which plot graticules for visual inspection of scaling, orientation, and other macroscopic characteristics of the projections.

There are also a number of other special-purpose test programs that are not automatically exercised by the test suite.

1.13 WCSLIB Fortran wrappers

The Fortran subdirectory contains wrappers, written in C, that allow Fortran programs to use WCSLIB. The wrappers have no associated C header files, nor C function prototypes, as they are only meant to be called by Fortran code. Hence the C code must be consulted directly to determine the argument lists. This resides in files with names of the form `*_f.c`. However, there are associated Fortran `INCLUDE` files that declare function return types and various parameter definitions. There are also `BLOCK DATA` modules, in files with names of the form `*_data.f`, used solely to initialise error message strings.

A prerequisite for using the wrappers is an understanding of the usage of the associated C routines, in particular the data structures they are based on. The principle difficulty in creating the wrappers was the need to manage these C structs from within Fortran, particularly as they contain pointers to allocated memory, pointers to C functions, and other structs that themselves contain similar entities.

To this end, routines have been provided to set and retrieve values of the various structs, for example `WCSPUT` and `WCSGET` for the wcsprm struct, and `CELPUT` and `CELGET` for the celprm struct. These must be used in conjunction with wrappers on the routines provided to manage the structs in C, for example `WCSINIT`, `WCSSUB`, `WCSCOPY`, `WCSFREE`, and `WCSPRT` which wrap wcsinit(), wcssub(), wcscopy(), wcsfree(), and wcsprt().

Compilers (e.g. gfortran) may warn of inconsistent usage of the third argument in the various `*PUT` and `*GET` routines, and as of gfortran 10, these warnings have been promoted to errors. Thus, type-specific variants are provided for each of the `*PUT` routines, `*PTI`, `*PTD`, and `*PTC` for *int*, *double*, or *char*[], and likewise `*GTI`, `*GTD`, and `*GTC` for the `*GET` routines. While, for brevity, we will here continue to refer to the `*PUT` and `*GET` routines, as compilers are generally becoming stricter, use of the type-specific variants is recommended.

The various `*PUT` and `*GET` routines are based on codes defined in Fortran include files (*.inc). If your Fortran compiler does not support the `INCLUDE` statement then you will need to include these manually in your code as necessary. Codes are defined as parameters with names like `WCS_CRPIX` which refers to wcsprm::crpix (if your Fortran compiler does not support long symbolic names then you will need to rename these).

The include files also contain parameters, such as `WCSLEN`, that define the length of an `INTEGER` array that must be declared to hold the struct. This length may differ for different platforms depending on how the C compiler aligns data within the structs. A test program for the C library, *twcs*, prints the size of the struct in *sizeof(int)* units and the values in the Fortran include files must equal or exceed these. On some platforms, such as Suns, it is important that the start of the `INTEGER` array be ***aligned on a `DOUBLE PRECISION` boundary***, otherwise a mysterious `BUS` error may result. This may be achieved via an `EQUIVALENCE` with a `DOUBLE PRECISION`

variable, or by sequencing variables in a COMMON block so that the INTEGER array follows immediately after a DOUBLE PRECISION variable.

The *PUT routines set only one element of an array at a time; the final one or two integer arguments of these routines specify 1-relative array indices (N.B. not 0-relative as in C). The one exception is the prjprm::pv array.

The *PUT routines also reset the *flag* element to signal that the struct needs to be reinitialized. Therefore, if you wanted to set wcsprm::flag itself to -1 prior to the first call to WCSINIT, for example, then that WCSPUT must be the last one before the call.

The *GET routines retrieve whole arrays at a time and expect array arguments of the appropriate length where necessary. Note that they do not initialize the structs, i.e. via wcsset(), prjset(), or whatever.

A basic coding fragment is

```
      INTEGER   LNGIDX, STATUS
      CHARACTER CTYPE1*72

      INCLUDE 'wcs.inc'

*     WCSLEN is defined as a parameter in wcs.inc.
      INTEGER   WCS(WCSLEN)
      DOUBLE PRECISION DUMMY
      EQUIVALENCE (WCS, DUMMY)

*     Allocate memory and set default values for 2 axes.
      STATUS = WCSPTI (WCS, WCS_FLAG, -1, 0, 0)
      STATUS = WCSINI (2, WCS)

*     Set CRPIX1, and CRPIX2; WCS_CRPIX is defined in wcs.inc.
      STATUS = WCSPTD (WCS, WCS_CRPIX, 512D0, 1, 0)
      STATUS = WCSPTD (WCS, WCS_CRPIX, 512D0, 2, 0)

*     Set PC1_2 to 5.0 (I = 1, J = 2).
      STATUS = WCSPTD (WCS, WCS_PC, 5D0, 1, 2)

*     Set CTYPE1 to 'RA---SIN'; N.B. must be given as CHARACTER*72.
      CTYPE1 = 'RA---SIN'
      STATUS = WCSPTC (WCS, WCS_CTYPE, CTYPE1, 1, 0)

*     Use an alternate method to set CTYPE2.
      STATUS = WCSPTC (WCS, WCS_CTYPE, 'DEC--SIN'//CHAR(0), 2, 0)

*     Set PV1_3 to -1.0 (I = 1, M = 3).
      STATUS = WCSPTD (WCS, WCS_PV, -1D0, 1, 3)

      etc.

*     Initialize.
      STATUS = WCSSET (WCS)
      IF (STATUS.NE.0) THEN
        CALL FLUSH (6)
        STATUS = WCSPERR (WCS, 'EXAMPLE: '//CHAR(0))
      ENDIF

*     Find the "longitude" axis.
      STATUS = WCSGTI (WCS, WCS_LNG, LNGIDX)

*     Free memory.
      STATUS = WCSFREE (WCS)
```

Refer to the various Fortran test programs for further programming examples. In particular, *twcs* and *twcsmix* show how to retrieve elements of the celprm and prjprm structs contained within the wcsprm struct.

Treatment of CHARACTER arguments in wrappers such as SPCTYPE, SPECX, and WCSSPTR, depends on whether they are given or returned. Where a CHARACTER variable is returned, its length must match the declared length in the definition of the C wrapper. The terminating null character in the C string, and all following it up

to the declared length, are replaced with blanks. If the Fortran CHARACTER variable were shorter than the declared length, an out-of-bounds memory access error would result. If longer, the excess, uninitialized, characters could contain garbage.

If the CHARACTER argument is given, a null-terminated CHARACTER variable may be provided as input, e.g. constructed using the Fortran CHAR(0) intrinsic as in the example code above. The wrapper makes a character-by-character copy, searching for a NULL character in the process. If it finds one, the copy terminates early, resulting in a valid C string. In this case any trailing blanks before the NULL character are preserved if it makes sense to do so, such as in setting a prefix for use by the *PERR wrappers, such as WCSPERR in the example above. If a NULL is not found, then the CHARACTER argument must be at least as long as the declared length, and any trailing blanks are stripped off. Should a CHARACTER argument exceed the declared length, the excess characters are ignored.

There is one exception to the above caution regarding CHARACTER arguments. The WCSLIB_VERSION wrapper is unusual in that it provides for the length of its CHARACTER argument to be specified, and only so many characters as fit within that length are returned.

Note that the data type of the third argument to the *PUT (or *PTI, *PTD, or *PTC) and *GET (or *GTI, *GTD, or *GTC) routines differs depending on the data type of the corresponding C struct member, be it *int*, *double*, or *char*[]. It is essential that the Fortran data type match that of the C struct for *int* and *double* types, and be a CHARACTER variable of the correct length for *char*[] types, or else be null-terminated, as in the coding example above. As a further example, in the two equivalent calls

```
STATUS = PRJGET (PRJ, PRJ_NAME, NAME)
STATUS = PRJGTC (PRJ, PRJ_NAME, NAME)
```

which return a character string, NAME must be a CHARACTER variable of length 40, as declared in the prjprm struct, no less and no more, the comments above pertaining to wrappers that contain CHARACTER arguments also applying here. However, a few exceptions have been made to simplify coding. The relevant *PUT (or *PTC) wrappers allow unterminated CHARACTER variables of less than the declared length for the following: prjprm::code (3 characters), spcprm::type (4 characters), spcprm::code (3 characters), and fitskeyid::name (8 characters). It doesn't hurt to specify longer CHARACTER variables, but the trailing characters will be ignored. Notwithstanding this simplification, the length of the corresponding variables in the *GET (or *GTC) wrappers must match the length declared in the struct.

When calling wrappers for C functions that print to *stdout*, such as WCSPRT, and WCSPERR, or that may print to *stderr*, such as WCSPIH, WCSBTH, WCSULEXE, or WCSUTRNE, it may be necessary to flush the Fortran I/O buffers beforehand so that the output appears in the correct order. The wrappers for these functions do call fflush(↩ NULL), but depending on the particular system, this may not succeed in flushing the Fortran I/O buffers. Most Fortran compilers provide the non-standard intrinsic FLUSH(), which is called with unit number 6 to flush *stdout* (as in the example above), and unit 0 for *stderr*.

A basic assumption made by the wrappers is that an INTEGER variable is no less than half the size of a DOUBLE PRECISION.

1.14 PGSBOX

PGSBOX, which is provided as a separate part of WCSLIB, is a PGPLOT routine (PGPLOT being a Fortran graphics library) that draws and labels curvilinear coordinate grids. Example PGSBOX grids can be seen at http↩ ://www.atnf.csiro.au/people/Mark.Calabretta/WCS/PGSBOX/index.html.

The prologue to pgsbox.f contains usage instructions. pgtest.f and cpgtest.c serve as test and demonstration programs in Fortran and C and also as well- documented examples of usage.

PGSBOX requires a separate routine, EXTERNAL NLFUNC, to define the coordinate transformation. Fortran subroutine PGCRFN (pgcrfn.f) is provided to define separable pairs of non-linear coordinate systems. Linear, logarithmic

and power-law axis types are currently defined; further types may be added as required. A C function, *pgwcsl_()*, with Fortran-like interface defines an NLFUNC that interfaces to WCSLIB 4.x for PGSBOX to draw celestial coordinate grids.

PGPLOT is implemented as a Fortran library with a set of C wrapper routines that are generated by a software tool. However, PGSBOX has a more complicated interface than any of the standard PGPLOT routines, especially in having an EXTERNAL function in its argument list. Consequently, PGSBOX is implemented in Fortran but with a hand-coded C wrapper, *cpgsbox()*.

As an example, in this suite the C test/demo program, *cpgtest*, calls the C wrapper, *cpgsbox()*, passing it a pointer to *pgwcsl_()*. In turn, *cpgsbox()* calls PGSBOX, which invokes *pgwcsl_()* as an EXTERNAL subroutine. In this sequence, a complicated C struct defined by *cpgtest* is passed through PGSBOX to *pgwcsl_()* as an INTEGER array.

While there are no formal standards for calling Fortran from C, there are some fairly well established conventions. Nevertheless, it's possible that you may need to modify the code if you use a combination of Fortran and C compilers with linkage conventions that differ from that of the GNU compilers, gcc and g77.

1.15 WCSLIB version numbers

The full WCSLIB/PGSBOX version number is composed of three integers in fields separated by periods:

- **Major**: the first number changes only when the ABI changes, a rare occurence (and the API never changes). Typically, the ABI changes when the contents of a struct change. For example, the contents of the *linprm* struct changed between 4.25.1 and 5.0.

  In practical terms, this number becomes the major version number of the WCSLIB sharable library, **libwcs.so.**<***major***>. To avoid possible segmentation faults or bus errors that may arise from the altered ABI, the dynamic (runtime) linker will not allow an application linked to a sharable library with a particular major version number to run with that of a different major version number.

  Application code must be recompiled and relinked to use a newer version of the WCSLIB sharable library with a new major version number.

- **Minor**: the second number changes when existing code is changed, whether due to added functionality or bug fixes. This becomes the minor version number of the WCSLIB sharable library, **libwcs.so.**<***major***>**.**<***minor***>.

  Because the ABI remains unchanged, older applications can use the new sharable library without needing to be recompiled, thus obtaining the benefit of bug fixes, speed enhancements, etc.

  Application code written subsequently to use the added functionality would, of course, need to be recompiled.

- **Patch**: the third number, which is often omitted, indicates a change to the build procedures, documentation, or test suite. It may also indicate changes to the utility applications (*wcsware*, *HPXcvt*, etc.), including the addition of new ones.

  However, the library itself, including the definitions in the header files, remains unaltered, so there is no point in recompiling applications.

The following describes what happens (or should happen) when WCSLIB's installation procedures are used on a typical Linux system using the GNU gcc compiler and GNU linker.

The sharable library should be installed as libwcs.so.<*major*>.<*minor*>, say libwcs.so.5.4 for concreteness, and a number of symbolic links created as follows:

```
libwcs.so     -> libwcs.so.5
libwcs.so.5   -> libwcs.so.5.4
libwcs.so.5.4
```

When an application is linked using '-lwcs', the linker finds libwcs.so and the symlinks lead it to libwcs.so.5.4. However, that library's SONAME is actually 'libwcs.so.5', by virtue of linker options used when the sharable library was created, as can be seen by running

```
readelf -d libwcs.so.5.4
```

Thus, when an application that was compiled and linked to libwcs.so.5.4 begins execution, the dynamic linker, ld.so, will attempt to bind it to libwcs.so.5, as can be seen by running

```
ldd <application>
```

Later, when WCSLIB 5.5 is installed, the library symbolic links will become

```
libwcs.so     -> libwcs.so.5
libwcs.so.5   -> libwcs.so.5.5
libwcs.so.5.4
libwcs.so.5.5
```

Thus, even without being recompiled, existing applications will link automatically to libwcs.so.5.5 at runtime. In fact, libwcs.so.5.4 would no longer be used and could be deleted.

If WCSLIB 6.0 were to be installed at some later time, then the libwcs.so.6 libraries would be used for new compilations. However, the libwcs.so.5 libraries must be left in place for existing executables that still require them:

```
libwcs.so     -> libwcs.so.6
libwcs.so.6   -> libwcs.so.6.0
libwcs.so.6.0
libwcs.so.5   -> libwcs.so.5.5
libwcs.so.5.5
```

5 Data Structure Documentation

5.1 auxprm Struct Reference

Additional auxiliary parameters.

`#include <wcs.h>`

Data Fields

- double rsun_ref
- double dsun_obs
- double crln_obs
- double hgln_obs
- double hglt_obs
- double a_radius
- double b_radius
- double c_radius
- double blon_obs
- double blat_obs
- double bdis_obs
- double dummy [2]

5.1.1 Detailed Description

Additional auxiliary parameters.

The **auxprm** struct holds auxiliary coordinate system information of a specialist nature. It is anticipated that this struct will expand in future to accomodate additional parameters.

All members of this struct are to be set by the user.

5.1.2 Field Documentation

rsun_ref

```
double auxprm::rsun_ref
```

(Given, auxiliary) Reference radius of the Sun used in coordinate calculations (m).

dsun_obs

```
double auxprm::dsun_obs
```

(Given, auxiliary) Distance between the centre of the Sun and the observer (m).

crln_obs

```
double auxprm::crln_obs
```

(Given, auxiliary) Carrington heliographic longitude of the observer (deg).

hgln_obs

```
double auxprm::hgln_obs
```

(Given, auxiliary) Stonyhurst heliographic longitude of the observer (deg).

hglt_obs

```
double auxprm::hglt_obs
```

(Given, auxiliary) Heliographic latitude (Carrington or Stonyhurst) of the observer (deg).

a_radius

```
double auxprm::a_radius
```

Length of the semi-major axis of a triaxial ellipsoid approximating the shape of a body (e.g. planet) in the solar system (m).

b_radius

```
double auxprm::b_radius
```

Length of the intermediate axis, normal to the semi-major and semi-minor axes, of a triaxial ellipsoid approximating the shape of a body (m).

c_radius

```
double auxprm::c_radius
```

Length of the semi-minor axis, normal to the semi-major axis, of a triaxial ellipsoid approximating the shape of a body (m).

blon_obs

```
double auxprm::blon_obs
```

Bodycentric longitude of the observer in the coordinate system fixed to the planet or other solar system body (deg, in range 0 to 360).

blat_obs

```
double auxprm::blat_obs
```

Bodycentric latitude of the observer in the coordinate system fixed to the planet or other solar system body (deg).

bdis_obs

```
double auxprm::bdis_obs
```

Bodycentric distance of the observer (m).

Global variable: const char ∗wcs_errmsg[] - Status return messages Error messages to match the status value returned from each function.

dummy

```
double auxprm::dummy[2]
```

5.2 celprm Struct Reference

Celestial transformation parameters.

```
#include <cel.h>
```

Data Fields

- int flag
- int offset
- double phi0
- double theta0
- double ref [4]
- struct prjprm prj
- double euler [5]
- int latpreq
- int isolat
- struct wcserr ∗ err
- void ∗ padding

5.2.1 Detailed Description

Celestial transformation parameters.

The **celprm** struct contains information required to transform celestial coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes and others are for internal use only.

Returned **celprm** struct members must not be modified by the user.

5.2.2 Field Documentation

flag

```
int celprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following **celprm** struct members are set or changed:

- celprm::offset,
- celprm::phi0,
- celprm::theta0,
- celprm::ref[4],
- celprm::prj:
  - prjprm::code,
  - prjprm::r0,
  - prjprm::pv[],
  - prjprm::phi0,
  - prjprm::theta0.

This signals the initialization routine, celset(), to recompute the returned members of the **celprm** struct. celset() will reset flag to indicate that this has been done.

offset

```
int celprm::offset
```

(*Given*) If true (non-zero), an offset will be applied to (x, y) to force (x, y) = (0,0) at the fiducial point, (ϕ_0, θ_0). Default is 0 (false).

phi0

```
double celprm::phi0
```

(*Given*) The native longitude, ϕ_0 [deg], and ...

theta0

```
double celprm::theta0
```

(*Given*) ... the native latitude, θ_0 [deg], of the fiducial point, i.e. the point whose celestial coordinates are given in celprm::ref[1:2]. If undefined (set to a magic value by prjini()) the initialization routine, celset(), will set this to a projection-specific default.

ref

```
double celprm::ref
```

(*Given*) The first pair of values should be set to the celestial longitude and latitude of the fiducial point [deg] - typically right ascension and declination. These are given by the **CRVAL**ia keywords in FITS.

(Given and returned) The second pair of values are the native longitude, $\phi_{\rm p}$ [deg], and latitude, $\theta_{\rm p}$ [deg], of the celestial pole (the latter is the same as the celestial latitude of the native pole, $\delta_{\rm p}$) and these are given by the FITS keywords **LONPOLE**a and **LATPOLE**a (or by **PV**i**_2**a and **PV**i**_3**a attached to the longitude axis which take precedence if defined).

LONPOLEa defaults to ϕ_0 (see above) if the celestial latitude of the fiducial point of the projection is greater than or equal to the native latitude, otherwise ϕ_0 + 180 [deg]. (This is the condition for the celestial latitude to increase in the same direction as the native latitude at the fiducial point.) ref[2] may be set to **UNDEFINED** (from wcsmath.h) or 999.0 to indicate that the correct default should be substituted.

$\theta_{\rm p}$, the native latitude of the celestial pole (or equally the celestial latitude of the native pole, $\delta_{\rm p}$) is often determined uniquely by **CRVAL**ia and **LONPOLE**a in which case **LATPOLE**a is ignored. However, in some circumstances there are two valid solutions for $\theta_{\rm p}$ and **LATPOLE**a is used to choose between them. **LATPOLE**a is set in ref[3] and the solution closest to this value is used to reset ref[3]. It is therefore legitimate, for example, to set ref[3] to +90.0 to choose the more northerly solution - the default if the **LATPOLE**a keyword is omitted from the FITS header. For the special case where the fiducial point of the projection is at native latitude zero, its celestial latitude is zero, and **LONPOLE**a = $\pm$ 90.0 then the celestial latitude of the native pole is not determined by the first three reference values and **LATPOLE**a specifies it completely.

The returned value, celprm::latpreq, specifies how **LATPOLE**a was actually used.

prj

```
struct prjprm celprm::prj
```

(Given and returned) Projection parameters described in the prologue to prj.h.

euler

```
double celprm::euler
```

(*Returned*) Euler angles and associated intermediaries derived from the coordinate reference values. The first three values are the Z-, X-, and Z'-Euler angles [deg], and the remaining two are the cosine and sine of the X-Euler angle.

latpreq

```
int celprm::latpreq
```

(*Returned*) For informational purposes, this indicates how the **LATPOLE**a keyword was used

- 0: Not required, $\theta_{\rm p}$ (== $\delta_{\rm p}$) was determined uniquely by the **CRVAL**ia and **LONPOLE**a keywords.
- 1: Required to select between two valid solutions of $\theta_{\rm p}$.
- 2: $\theta_{\rm p}$ was specified solely by **LATPOLE**a.

isolat

```
int celprm::isolat
```

(*Returned*) True if the spherical rotation preserves the magnitude of the latitude, which occurs iff the axes of the native and celestial coordinates are coincident. It signals an opportunity to cache intermediate calculations common to all elements in a vector computation.

err

```
struct wcserr * celprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding

```
void * celprm::padding
```

(An unused variable inserted for alignment purposes only.)

Global variable: const char *cel_errmsg[] - Status return messages Status messages to match the status value returned from each function.

5.3 disprm Struct Reference

Distortion parameters.

```
#include <dis.h>
```

Data Fields

- int flag
- int naxis
- char(* dtype)[72]
- int ndp
- int ndpmax
- struct dpkey * dp
- double totdis
- double * maxdis
- int * docorr
- int * Nhat
- int ** axmap
- double ** offset
- double ** scale
- int ** iparm
- double ** dparm
- int i_naxis
- int ndis
- struct wcserr * err
- int(** disp2x)(DISP2X_ARGS)
- int(** disx2p)(DISX2P_ARGS)
- int m_flag
- int m_naxis
- char(* m_dtype)[72]
- struct dpkey * m_dp
- double * m_maxdis

5.3.1 Detailed Description

Distortion parameters.

The **disprm** struct contains all of the information required to apply a set of distortion functions. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). While the addresses of the arrays themselves may be set by disinit() if it (optionally) allocates memory, their contents must be set by the user.

5.3.2 Field Documentation

flag

```
int disprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following members of the **disprm** struct are set or modified:

- disprm::naxis,
- disprm::dtype,
- disprm::ndp,
- disprm::dp.

This signals the initialization routine, disset(), to recompute the returned members of the **disprm** struct. disset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag must be set to -1 when disinit() is called for the first time for a particular **disprm** struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

naxis

```
int disprm::naxis
```

(Given or returned) Number of pixel and world coordinate elements.

If disinit() is used to initialize the **disprm** struct (as would normally be the case) then it will set naxis from the value passed to it as a function argument. The user should not subsequently modify it.

dtype

```
disprm::dtype
```

(*Given*) Pointer to the first element of an array of char[72] containing the name of the distortion function for each axis.

ndp

```
int disprm::ndp
```

(*Given*) The number of entries in the disprm::dp[] array.

ndpmax

```
int disprm::ndpmax
```

(*Given*) The length of the disprm::dp[] array.

ndpmax will be set by disinit() if it allocates memory for disprm::dp[], otherwise it must be set by the user. See also disndp().

dp

```
struct dpkey disprm::dp
```

(*Given*) Address of the first element of an array of length ndpmax of dpkey structs.

As a FITS header parser encounters each **DP**`ja` or **DQ**`ia` keyword it should load it into a dpkey struct in the array and increment ndp. However, note that a single **disprm** struct must hold only **DP**`ja` or **DQ**`ia` keyvalues, not both. disset() interprets them as required by the particular distortion function.

totdis

```
double disprm::totdis
```

(*Given*) The maximum absolute value of the combination of all distortion functions specified as an offset in pixel coordinates computed over the whole image.

It is not necessary to reset the **disprm** struct (via disset()) when disprm::totdis is changed.

maxdis

```
double * disprm::maxdis
```

(*Given*) Pointer to the first element of an array of double specifying the maximum absolute value of the distortion for each axis computed over the whole image.

It is not necessary to reset the **disprm** struct (via disset()) when disprm::maxdis is changed.

docorr

```
int * disprm::docorr
```

(*Returned*) Pointer to the first element of an array of int containing flags that indicate the mode of correction for each axis.

If docorr is zero, the distortion function returns the corrected coordinates directly. Any other value indicates that the distortion function computes a correction to be added to pixel coordinates (prior distortion) or intermediate pixel coordinates (sequent distortion).

Nhat

```
int * disprm::Nhat
```

(*Returned*) Pointer to the first element of an array of int containing the number of coordinate axes that form the independent variables of the distortion function for each axis.

axmap

```
int ** disprm::axmap
```

(*Returned*) Pointer to the first element of an array of int∗ containing pointers to the first elements of the axis mapping arrays for each axis.

An axis mapping associates the independent variables of a distortion function with the 0-relative image axis number. For example, consider an image with a spectrum on the first axis (axis 0), followed by RA (axis 1), Dec (axis2), and time (axis 3) axes. For a distortion in (RA,Dec) and no distortion on the spectral or time axes, the axis mapping arrays, axmap[j][], would be

```
j=0: [-1, -1, -1, -1]   ...no  distortion on spectral axis,
  1: [ 1,  2, -1, -1]   ...RA  distortion depends on RA and Dec,
  2: [ 2,  1, -1, -1]   ...Dec distortion depends on Dec and RA,
  3: [-1, -1, -1, -1]   ...no  distortion on time axis,
```

where -1 indicates that there is no corresponding independent variable.

offset

```
double ** disprm::offset
```

(*Returned*) Pointer to the first element of an array of double∗ containing pointers to the first elements of arrays of offsets used to renormalize the independent variables of the distortion function for each axis.

The offsets are subtracted from the independent variables before scaling.

scale

```
double ** disprm::scale
```

(*Returned*) Pointer to the first element of an array of double* containing pointers to the first elements of arrays of scales used to renormalize the independent variables of the distortion function for each axis.

The scale is applied to the independent variables after the offsets are subtracted.

iparm

```
int ** disprm::iparm
```

(*Returned*) Pointer to the first element of an array of int* containing pointers to the first elements of the arrays of integer distortion parameters for each axis.

dparm

```
double ** disprm::dparm
```

(*Returned*) Pointer to the first element of an array of double* containing pointers to the first elements of the arrays of floating point distortion parameters for each axis.

i_naxis

```
int disprm::i_naxis
```

(*Returned*) Dimension of the internal arrays (normally equal to naxis).

ndis

```
int disprm::ndis
```

(*Returned*) The number of distortion functions.

err

```
struct wcserr * disprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

disp2x

```
int(** disprm::disp2x)(DISP2X_ARGS)
```

(For internal use only.)

disx2p

```
int(** disprm::disx2p)(DISX2P_ARGS)
```

(For internal use only.)

m_flag

```
int disprm::m_flag
```

(For internal use only.)

m_naxis

```
int disprm::m_naxis
```

(For internal use only.)

m_dtype

```
disprm::m_dtype
```

(For internal use only.)

m_dp

```
double ** disprm::m_dp
```

(For internal use only.)

m_maxdis

```
double * disprm::m_maxdis
```

(For internal use only.)

5.4 dpkey Struct Reference

Store for **DP**`ja` and **DQ**`ia` keyvalues.

```
#include <dis.h>
```

Data Fields

- char field [72]
- int j
- int type
- union {
    int i
    double f
  } value

5.4.1 Detailed Description

Store for **DP**`ja` and **DQ**`ia` keyvalues.

The **dpkey** struct is used to pass the parsed contents of **DP**`ja` or **DQ**`ia` keyrecords to disset() via the disprm struct. A disprm struct must hold only **DP**`ja` or **DQ**`ia` keyvalues, not both.

All members of this struct are to be set by the user.

5.4.2 Field Documentation

field

```
char dpkey::field
```

(*Given*) The full field name of the record, including the keyword name. Note that the colon delimiter separating the field name and the value in record-valued keyvalues is not part of the field name. For example, in the following:
```
DP3A = 'AXIS.1: 2'
```

the full record field name is "DP3A**.AXIS.**1", and the record's value is 2.

j

```
int dpkey::j
```

(*Given*) Axis number (1-relative), i.e. the j in **DP**`ja` or i in **DQ**`ia`.

type

```
int dpkey::type
```

(*Given*) The data type of the record's value

- 0: Integer (stored as an int),
- 1: Floating point (stored as a double).

i

```
int dpkey::i
```

f

```
double dpkey::f
```

value

```
union dpkey::value
```

(*Given*) A union comprised of

- dpkey::i,
- dpkey::f,

the record's value.

5.5 fitskey Struct Reference

Keyword/value information.

```
#include <fitshdr.h>
```

Data Fields

- int keyno
- int keyid
- int status
- char keyword [12]
- int type
- int padding
- union {
    int i
    int64 k
    int l [8]
    double f
    double c [2]
    char s [72]
  } keyvalue
- int ulen
- char comment [84]

5.5.1 Detailed Description

Keyword/value information.

fitshdr() returns an array of **fitskey** structs, each of which contains the result of parsing one FITS header keyrecord. All members of the **fitskey** struct are returned by fitshdr(), none are given by the user.

5.5.2 Field Documentation

keyno

```
int fitskey::keyno
```

(*Returned*) Keyrecord number (1-relative) in the array passed as input to fitshdr(). This will be negated if the keyword matched any specified in the keyids[] index.

keyid

```
int fitskey::keyid
```

(*Returned*) Index into the first entry in keyids[] with which the keyrecord matches, else -1.

status

```
int fitskey::status
```

(*Returned*) Status flag bit-vector for the header keyrecord employing the following bit masks defined as preprocessor macros:

- FITSHDR_KEYWORD: Illegal keyword syntax.
- FITSHDR_KEYVALUE: Illegal keyvalue syntax.
- FITSHDR_COMMENT: Illegal keycomment syntax.
- FITSHDR_KEYREC: Illegal keyrecord, e.g. an **END** keyrecord with trailing text.
- FITSHDR_TRAILER: Keyrecord following a valid **END** keyrecord.

The header keyrecord is syntactically correct if no bits are set.

keyword

```
char fitskey::keyword
```

(*Returned*) Keyword name, null-filled for keywords of less than eight characters (trailing blanks replaced by nulls).

Use
```
sprintf(dst, "%.8s", keyword)
```

to copy it to a character array with null-termination, or
```
sprintf(dst, "%8.8s", keyword)
```

to blank-fill to eight characters followed by null-termination.

type

```
int fitskey::type
```

(*Returned*) Keyvalue data type:

- 0: No keyvalue (both the value and type are undefined).
- 1: Logical, represented as int.
- 2: 32-bit signed integer.
- 3: 64-bit signed integer (see below).
- 4: Very long integer (see below).
- 5: Floating point (stored as double).
- 6: Integer complex (stored as double[2]).
- 7: Floating point complex (stored as double[2]).
- 8: String.
- 8+10∗n: Continued string (described below and in fitshdr() note 2).

A negative type indicates that a syntax error was encountered when attempting to parse a keyvalue of the particular type.

Comments on particular data types:

- 64-bit signed integers lie in the range
  ```
  (-9223372036854775808 <= int64 <  -2147483648) ||
           (+2147483647 <  int64 <= +9223372036854775807)
  ```
  A native 64-bit data type may be defined via preprocessor macro WCSLIB_INT64 defined in wcsconfig.h, e.g. as 'long long int'; this will be typedef'd to 'int64' here. If WCSLIB_INT64 is not set, then int64 is typedef'd to int[3] instead and fitskey::keyvalue is to be computed as
  ```
  ((keyvalue.k[2]) * 1000000000 +
    keyvalue.k[1]) * 1000000000 +
    keyvalue.k[0]
  ```
  and may reported via
  ```
  if (keyvalue.k[2]) {
    printf("%d%09d%09d", keyvalue.k[2], abs(keyvalue.k[1]),
                         abs(keyvalue.k[0]));
  } else {
    printf("%d%09d", keyvalue.k[1], abs(keyvalue.k[0]));
  }
  ```
  where keyvalue.k[0] and keyvalue.k[1] range from -999999999 to +999999999.
- Very long integers, up to 70 decimal digits in length, are encoded in keyvalue.l as an array of int[8], each of which stores 9 decimal digits. fitskey::keyvalue is to be computed as
  ```
  (((((((keyvalue.l[7]) * 1000000000 +
         keyvalue.l[6]) * 1000000000 +
         keyvalue.l[5]) * 1000000000 +
         keyvalue.l[4]) * 1000000000 +
         keyvalue.l[3]) * 1000000000 +
         keyvalue.l[2]) * 1000000000 +
         keyvalue.l[1]) * 1000000000 +
         keyvalue.l[0]
  ```
- Continued strings are not reconstructed, they remain split over successive **fitskey** structs in the keys[] array returned by fitshdr(). fitskey::keyvalue data type, 8 + 10n, indicates the segment number, n, in the continuation.

padding

```
int fitskey::padding
```

(An unused variable inserted for alignment purposes only.)

i

```
int fitskey::i
```

(*Returned*) Logical (fitskey::type == 1) and 32-bit signed integer (fitskey::type == 2) data types in the fitskey::keyvalue union.

k

```
int64 fitskey::k
```

(*Returned*) 64-bit signed integer (fitskey::type == 3) data type in the fitskey::keyvalue union.

l

```
int fitskey::l
```

(*Returned*) Very long integer (fitskey::type == 4) data type in the fitskey::keyvalue union.

f

```
double fitskey::f
```

(*Returned*) Floating point (fitskey::type == 5) data type in the fitskey::keyvalue union.

c

```
double fitskey::c
```

(*Returned*) Integer and floating point complex (fitskey::type == 6 || 7) data types in the fitskey::keyvalue union.

s

```
char fitskey::s
```

(*Returned*) Null-terminated string (fitskey::type == 8) data type in the fitskey::keyvalue union.

keyvalue

```
union fitskey::keyvalue
```

(*Returned*) A union comprised of

- fitskey::i,
- fitskey::k,
- fitskey::l,
- fitskey::f,
- fitskey::c,
- fitskey::s,

used by the **fitskey** struct to contain the value associated with a keyword.

ulen

```
int fitskey::ulen
```

(*Returned*) Where a keycomment contains a units string in the standard form, e.g. [m/s], the ulen member indicates its length, inclusive of square brackets. Otherwise ulen is zero.

comment

```
char fitskey::comment
```

(*Returned*) Keycomment, i.e. comment associated with the keyword or, for keyrecords rejected because of syntax errors, the compete keyrecord itself with null-termination.

Comments are null-terminated with trailing spaces removed. Leading spaces are also removed from keycomments (i.e. those immediately following the '**/**' character), but not from **COMMENT** or **HISTORY** keyrecords or keyrecords without a value indicator ("**=** " in columns 9-80).

5.6 fitskeyid Struct Reference

Keyword indexing.

```
#include <fitshdr.h>
```

Data Fields

- char name [12]
- int count
- int idx [2]

5.6.1 Detailed Description

Keyword indexing.

fitshdr() uses the **fitskeyid** struct to return indexing information for specified keywords. The struct contains three members, the first of which, fitskeyid::name, must be set by the user with the remainder returned by fitshdr().

5.6.2 Field Documentation

name

```
char fitskeyid::name
```

(*Given*) Name of the required keyword. This is to be set by the user; the '.' character may be used for wildcarding. Trailing blanks will be replaced with nulls.

count

```
int fitskeyid::count
```

(*Returned*) The number of matches found for the keyword.

idx

```
int fitskeyid::idx
```

(*Returned*) Indices into keys[], the array of fitskey structs returned by fitshdr(). Note that these are 0-relative array indices, not keyrecord numbers.

If the keyword is found in the header the first index will be set to the array index of its first occurrence, otherwise it will be set to -1.

If multiples of the keyword are found, the second index will be set to the array index of its last occurrence, otherwise it will be set to -1.

5.7 linprm Struct Reference

Linear transformation parameters.

```
#include <lin.h>
```

Data Fields

- int flag
- int naxis
- double * crpix
- double * pc
- double * cdelt
- struct disprm * dispre
- struct disprm * disseq
- double * piximg
- double * imgpix
- int i_naxis
- int unity
- int affine
- int simple
- struct wcserr * err
- double * tmpcrd
- int m_flag
- int m_naxis
- double * m_crpix
- double * m_pc
- double * m_cdelt
- struct disprm * m_dispre
- struct disprm * m_disseq

5.7.1 Detailed Description

Linear transformation parameters.

The **linprm** struct contains all of the information required to perform a linear transformation. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*).

5.7.2 Field Documentation

flag

```
int linprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following members of the **linprm** struct are set or modified:

- linprm::naxis (q.v., not normally set by the user),
- linprm::pc,
- linprm::cdelt,
- linprm::dispre.
- linprm::disseq.

This signals the initialization routine, linset(), to recompute the returned members of the **linprm** struct. linset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag should be set to -1 when lininit() is called for the first time for a particular **linprm** struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

naxis

```
int linprm::naxis
```

(Given or returned) Number of pixel and world coordinate elements.

If lininit() is used to initialize the **linprm** struct (as would normally be the case) then it will set naxis from the value passed to it as a function argument. The user should not subsequently modify it.

crpix

```
double * linprm::crpix
```

(*Given*) Pointer to the first element of an array of double containing the coordinate reference pixel, **CRPIX**ja.

It is not necessary to reset the **linprm** struct (via linset()) when linprm::crpix is changed.

pc

```
double * linprm::pc
```

(*Given*) Pointer to the first element of the **PC**i_ja (pixel coordinate) transformation matrix. The expected order is

```
struct linprm lin;
lin.pc = {PC1_1, PC1_2, PC2_1, PC2_2};
```

This may be constructed conveniently from a 2-D array via

```
double m[2][2] = {{PC1_1, PC1_2},
                  {PC2_1, PC2_2}};
```

which is equivalent to

```
double m[2][2];
m[0][0] = PC1_1;
m[0][1] = PC1_2;
m[1][0] = PC2_1;
m[1][1] = PC2_2;
```

The storage order for this 2-D array is the same as for the 1-D array, whence

```
lin.pc = *m;
```

would be legitimate.

cdelt

```
double * linprm::cdelt
```

(*Given*) Pointer to the first element of an array of double containing the coordinate increments, **CDELT**ia.

dispre

```
struct disprm * linprm::dispre
```

(*Given*) Pointer to a disprm struct holding parameters for prior distortion functions, or a null (0x0) pointer if there are none.

Function lindist() may be used to assign a disprm pointer to a **linprm** struct, allowing it to take control of any memory allocated for it, as in the following example:

```
void add_distortion(struct linprm *lin)
{
  struct disprm *dispre;

  dispre = malloc(sizeof(struct disprm));
  dispre->flag = -1;
  lindist(1, lin, dispre, ndpmax);
    :
   (Set up dispre.)
    :

  return;
}
```

Here, after the distortion function parameters etc. are copied into dispre, dispre is assigned using lindist() which takes control of the allocated memory. It will be freed later when linfree() is invoked on the **linprm** struct.

Consider also the following erroneous code:

```
void bad_code(struct linprm *lin)
{
  struct disprm dispre;

  dispre.flag = -1;
  lindist(1, lin, &dispre, ndpmax);   // WRONG.
    :

  return;
}
```

Here, dispre is declared as a struct, rather than a pointer. When the function returns, dispre will go out of scope and its memory will most likely be reused, thereby trashing its contents. Later, a segfault will occur when linfree() tries to free dispre's stale address.

disseq

```
struct disprm * linprm::disseq
```

(*Given*) Pointer to a disprm struct holding parameters for sequent distortion functions, or a null (0x0) pointer if there are none.

Refer to the comments and examples given for disprm::dispre.

piximg

```
double * linprm::piximg
```

(*Returned*) Pointer to the first element of the matrix containing the product of the **CDELT**ia diagonal matrix and the **PC**i_ja matrix.

imgpix

```
double * linprm::imgpix
```

(*Returned*) Pointer to the first element of the inverse of the linprm::piximg matrix.

i_naxis

```
int linprm::i_naxis
```

(*Returned*) The dimension of linprm::piximg and linprm::imgpix (normally equal to naxis).

unity

```
int linprm::unity
```

(*Returned*) True if the linear transformation matrix is unity.

affine

```
int linprm::affine
```

(*Returned*) True if there are no distortions.

simple

```
int linprm::simple
```

(*Returned*) True if unity and no distortions.

err

```
struct wcserr * linprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

tmpcrd

```
double * linprm::tmpcrd
```

(For internal use only.)

m_flag

```
int linprm::m_flag
```

(For internal use only.)

m_naxis

```
int linprm::m_naxis
```

(For internal use only.)

m_crpix

```
double * linprm::m_crpix
```

(For internal use only.)

m_pc

```
double * linprm::m_pc
```

(For internal use only.)

m_cdelt

```
double * linprm::m_cdelt
```

(For internal use only.)

m_dispre

```
struct disprm * linprm::m_dispre
```

(For internal use only.)

m_disseq

```
struct disprm * linprm::m_disseq
```

(For internal use only.)

5.8 prjprm Struct Reference

Projection parameters.

- void * padding
- double w [10]
- int m
- int n
- int(* prjx2s)(PRJX2S_ARGS)
- int(* prjs2x)(PRJS2X_ARGS)

5.8.1 Detailed Description

Projection parameters.

The **prjprm** struct contains all information needed to project or deproject native spherical coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes while others are for internal use only.

5.8.2 Field Documentation

flag

```
int prjprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following **prjprm** struct members are set or changed:

- prjprm::code,
- prjprm::r0,
- prjprm::pv[],
- prjprm::phi0,
- prjprm::theta0.

This signals the initialization routine (prjset() or **???set()**) to recompute the returned members of the **prjprm** struct. flag will then be reset to indicate that this has been done.

Note that flag need not be reset when prjprm::bounds is changed.

code

```
char prjprm::code
```

(*Given*) Three-letter projection code defined by the FITS standard.

r0

```
double prjprm::r0
```

(*Given*) The radius of the generating sphere for the projection, a linear scaling parameter. If this is zero, it will be reset to its default value of $180^\circ/\pi$ (the value for FITS WCS).

pv

```
double prjprm::pv
```

(*Given*) Projection parameters. These correspond to the **PV**i_ma keywords in FITS, so pv[0] is **PV**i_**0**a, pv[1] is **PV**i_**1**a, etc., where i denotes the latitude-like axis. Many projections use pv[1] (**PV**i_**1**a), some also use pv[2] (**PV**i_**2**a) and **SZP** uses pv[3] (**PV**i_**3**a). **ZPN** is currently the only projection that uses any of the others.

Usage of the pv[] array as it applies to each projection is described in the prologue to each trio of projection routines in prj.c.

phi0

```
double prjprm::phi0
```

(*Given*) The native longitude, ϕ_0 [deg], and ...

theta0

```
double prjprm::theta0
```

(*Given*) ... the native latitude, θ_0 [deg], of the reference point, i.e. the point (x, y) = (0,0). If undefined (set to a magic value by prjini()) the initialization routine will set this to a projection-specific default.

bounds

```
int prjprm::bounds
```

(*Given*) Controls bounds checking. If bounds&1 then enable strict bounds checking for the spherical-to-Cartesian (s2x) transformation for the **AZP**, **SZP**, **TAN**, **SIN**, **ZPN**, and **COP** projections. If bounds&2 then enable strict bounds checking for the Cartesian-to-spherical transformation (x2s) for the **HPX** and XPH projections. If bounds&4 then the Cartesian- to-spherical transformations (x2s) will invoke prjbchk() to perform bounds checking on the computed native coordinates, with a tolerance set to suit each projection. bounds is set to 7 by prjini() by default which enables all checks. Zero it to disable all checking.

It is not necessary to reset the **prjprm** struct (via prjset() or **???set()**) when prjprm::bounds is changed.

The remaining members of the **prjprm** struct are maintained by the setup routines and must not be modified elsewhere:

name

```
char prjprm::name
```

(*Returned*) Long name of the projection.

Provided for information only, not used by the projection routines.

category

```
int prjprm::category
```

(*Returned*) Projection category matching the value of the relevant global variable:

- ZENITHAL,
- CYLINDRICAL,
- PSEUDOCYLINDRICAL,
- CONVENTIONAL,
- CONIC,
- POLYCONIC,
- QUADCUBE, and
- HEALPIX.

The category name may be identified via the prj_categories character array, e.g.

```
struct prjprm prj;
  ...
printf("%s\n", prj_categories[prj.category]);
```

Provided for information only, not used by the projection routines.

pvrange

```
int prjprm::pvrange
```

(*Returned*) Range of projection parameter indices: 100 times the first allowed index plus the number of parameters, e.g. **TAN** is 0 (no parameters), **SZP** is 103 (1 to 3), and **ZPN** is 30 (0 to 29).

Provided for information only, not used by the projection routines.

simplezen

```
int prjprm::simplezen
```

(*Returned*) True if the projection is a radially-symmetric zenithal projection.

Provided for information only, not used by the projection routines.

equiareal

```
int prjprm::equiareal
```

(*Returned*) True if the projection is equal area.

Provided for information only, not used by the projection routines.

conformal

```
int prjprm::conformal
```

(*Returned*) True if the projection is conformal.

Provided for information only, not used by the projection routines.

global

```
int prjprm::global
```

(*Returned*) True if the projection can represent the whole sphere in a finite, non-overlapped mapping.

Provided for information only, not used by the projection routines.

divergent

```
int prjprm::divergent
```

(*Returned*) True if the projection diverges in latitude.

Provided for information only, not used by the projection routines.

x0

```
double prjprm::x0
```

(*Returned*) The offset in x,and ...

y0

```
double prjprm::y0
```

(*Returned*) ... the offset in y used to force (x, y) = (0,0) at (ϕ_0, θ_0).

err

```
struct wcserr * prjprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding

```
void * prjprm::padding
```

(An unused variable inserted for alignment purposes only.)

w

```
double prjprm::w
```

(*Returned*) Intermediate floating-point values derived from the projection parameters, cached here to save recomputation.

Usage of the w[] array as it applies to each projection is described in the prologue to each trio of projection routines in prj.c.

m

```
int prjprm::m
```

n

```
int prjprm::n
```

(*Returned*) Intermediate integer value (used only for the **ZPN** and **HPX** projections).

prjx2s

```
prjprm::prjx2s
```

(*Returned*) Pointer to the spherical projection ...

prjs2x

```
prjprm::prjs2x
```

(*Returned*) ... and deprojection routines.

5.9 pscard Struct Reference

Store for **PS**i_ma keyrecords.

```
#include <wcs.h>
```

Data Fields

- int i
- int m
- char value [72]

5.9.1 Detailed Description

Store for **PS**i_ma keyrecords.

The **pscard** struct is used to pass the parsed contents of **PS**i_ma keyrecords to wcsset() via the wcsprm struct.

All members of this struct are to be set by the user.

5.9.2 Field Documentation

i

```
int pscard::i
```

(*Given*) Axis number (1-relative), as in the FITS **PS**i_ma keyword.

m

```
int pscard::m
```

(*Given*) Parameter number (non-negative), as in the FITS **PS**i_ma keyword.

value

```
char pscard::value
```

(*Given*) Parameter value.

5.10 pvcard Struct Reference

Store for **PV**i_ma keyrecords.

```
#include <wcs.h>
```

Data Fields

- int i
- int m
- double value

5.10.1 Detailed Description

Store for **PV**i_ma keyrecords.

The **pvcard** struct is used to pass the parsed contents of **PV**i_ma keyrecords to wcsset() via the wcsprm struct.

All members of this struct are to be set by the user.

5.10.2 Field Documentation

i

```
int pvcard::i
```

(*Given*) Axis number (1-relative), as in the FITS **PV**i_ma keyword. If i == 0, wcsset() will replace it with the latitude axis number.

m

```
int pvcard::m
```

(*Given*) Parameter number (non-negative), as in the FITS **PV**i_ma keyword.

value

```
double pvcard::value
```

(*Given*) Parameter value.

5.11 spcprm Struct Reference

Spectral transformation parameters.

```
#include <spc.h>
```

Data Fields

- int flag
- char type [8]
- char code [4]
- double crval
- double restfrq
- double restwav
- double pv [7]
- double w [6]
- int isGrism
- int padding1
- struct wcserr * err
- void * padding2
- int(* spxX2P)(SPX_ARGS)
- int(* spxP2S)(SPX_ARGS)
- int(* spxS2P)(SPX_ARGS)
- int(* spxP2X)(SPX_ARGS)

5.11.1 Detailed Description

Spectral transformation parameters.

The **spcprm** struct contains information required to transform spectral coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes while others are for internal use only.

5.11.2 Field Documentation

flag

```
int spcprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following **spcprm** structure members are set or changed:

- spcprm::type,
- spcprm::code,
- spcprm::crval,
- spcprm::restfrq,
- spcprm::restwav,
- spcprm::pv[].

This signals the initialization routine, spcset(), to recompute the returned members of the **spcprm** struct. spcset() will reset flag to indicate that this has been done.

type

```
char spcprm::type
```

(*Given*) Four-letter spectral variable type, e.g "ZOPT" for **CTYPE**`ia` = **'ZOPT-F2W'**. (Declared as char[8] for alignment reasons.)

code

```
char spcprm::code
```

(*Given*) Three-letter spectral algorithm code, e.g "F2W" for **CTYPE**`ia` = **'ZOPT-F2W'**.

crval

```
double spcprm::crval
```

(*Given*) Reference value (**CRVAL**`ia`), SI units.

restfrq

```
double spcprm::restfrq
```

(*Given*) The rest frequency [Hz], and ...

restwav

```
double spcprm::restwav
```

(*Given*) ... the rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero. Neither are required if the X and S spectral variables are both wave-characteristic, or both velocity-characteristic, types.

pv

```
double spcprm::pv
```

(*Given*) Grism parameters for '**GRI**' and '**GRA**' algorithm codes:

- 0: G, grating ruling density.
- 1: m, interference order.
- 2: α, angle of incidence [deg].
- 3: n_r, refractive index at the reference wavelength, λ_r.
- 4: n'_r, $dn/d\lambda$ at the reference wavelength, λ_r (/m).
- 5: ϵ, grating tilt angle [deg].
- 6: θ, detector tilt angle [deg].

The remaining members of the **spcprm** struct are maintained by spcset() and must not be modified elsewhere:

w

```
double spcprm::w
```

(*Returned*) Intermediate values:

- 0: Rest frequency or wavelength (SI).
- 1: The value of the X-type spectral variable at the reference point (SI units).
- 2: dX/dS at the reference point (SI units).

The remainder are grism intermediates.

isGrism

```
int spcprm::isGrism
```

(*Returned*) Grism coordinates?

- 0: no,
- 1: in vacuum,
- 2: in air.

padding1

```
int spcprm::padding1
```

(An unused variable inserted for alignment purposes only.)

err

```
struct wcserr * spcprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding2

```
void * spcprm::padding2
```

(An unused variable inserted for alignment purposes only.)

spxX2P

```
spcprm::spxX2P
```

(*Returned*) The first and ...

spxP2S

spcprm::spxP2S

(*Returned*) ... the second of the pointers to the transformation functions in the two-step algorithm chain $X \rightsquigarrow P \rightarrow S$ in the pixel-to-spectral direction where the non-linear transformation is from X to P. The argument list, SPX_ARGS, is defined in spx.h.

spxS2P

spcprm::spxS2P

(*Returned*) The first and ...

spxP2X

spcprm::spxP2X

(*Returned*) ... the second of the pointers to the transformation functions in the two-step algorithm chain $S \rightarrow P \rightsquigarrow X$ in the spectral-to-pixel direction where the non-linear transformation is from P to X. The argument list, SPX_ARGS, is defined in spx.h.

5.12.1 Detailed Description

Spectral variables and their derivatives.

The **spxprm** struct contains the value of all spectral variables and their derivatives. It is used solely by specx() which constructs it from information provided via its function arguments.

This struct should be considered read-only, no members need ever be set nor should ever be modified by the user.

5.12.2 Field Documentation

restfrq

```
double spxprm::restfrq
```

(*Returned*) Rest frequency [Hz].

restwav

```
double spxprm::restwav
```

(*Returned*) Rest wavelength [m].

wavetype

```
int spxprm::wavetype
```

(*Returned*) True if wave types have been computed, and ...

velotype

```
int spxprm::velotype
```

(*Returned*) ... true if velocity types have been computed; types are defined below.

If one or other of spxprm::restfrq and spxprm::restwav is given (non-zero) then all spectral variables may be computed. If both are given, restfrq is used. If restfrq and restwav are both zero, only wave characteristic xor velocity type spectral variables may be computed depending on the variable given. These flags indicate what is available.

freq

```
double spxprm::freq
```

(*Returned*) Frequency [Hz] (*wavetype*).

afrq

```
double spxprm::afrq
```

(*Returned*) Angular frequency [rad/s] (*wavetype*).

ener

```
double spxprm::ener
```

(*Returned*) Photon energy [J] (*wavetype*).

wavn

```
double spxprm::wavn
```

(*Returned*) Wave number [/m] (*wavetype*).

```

(*Returned*) ... vice versa [m s] (*wavetype*).

dfreqawav

```
double spxprm::dfreqawav
```

(*Returned*) Derivative of frequency with respect to air wavelength, [/m/s], and ...

dawavfreq

```
double spxprm::dawavfreq
```

(*Returned*) ... vice versa [m s] (*wavetype*).

dfreqvelo

```
double spxprm::dfreqvelo
```

(*Returned*) Derivative of frequency with respect to relativistic velocity [/m], and ...

dvelofreq

```
double spxprm::dvelofreq
```

(*Returned*) ... vice versa [m] (*wavetype* && *velotype*).

dwavevopt

```
double spxprm::dwavevopt
```

(*Returned*) Derivative of vacuum wavelength with respect to optical velocity [s], and ...

dvoptwave

```
double spxprm::dvoptwave
```

(*Returned*) ... vice versa [/s] (*wavetype* && *velotype*).

dwavezopt

```
double spxprm::dwavezopt
```

(*Returned*) Derivative of vacuum wavelength with respect to redshift [m], and ...

dzoptwave

```
double spxprm::dzoptwave
```

(*Returned*) ... vice versa [/m] (*wavetype* && *velotype*).

dwaveawav

```
double spxprm::dwaveawav
```

(*Returned*) Derivative of vacuum wavelength with respect to air wavelength [dimensionless], and ...

dawavwave

```
double spxprm::dawavwave
```

(*Returned*) ... vice versa [dimensionless] (*wavetype*).

dwavevelo

```
double spxprm::dwavevelo
```

(*Returned*) Derivative of vacuum wavelength with respect to relativistic velocity [s], and ...

dvelowave

```
double spxprm::dvelowave
```

(*Returned*) ... vice versa [/s] (*wavetype* && *velotype*).

dawavvelo

```
double spxprm::dawavvelo
```

(*Returned*) Derivative of air wavelength with respect to relativistic velocity [s], and ...

dveloawav

```
double spxprm::dveloawav
```

(*Returned*) ... vice versa [/s] (*wavetype* && *velotype*).

dvelobeta

```
double spxprm::dvelobeta
```

(*Returned*) Derivative of relativistic velocity with respect to relativistic beta [m/s] (constant, $= c$, the speed of light in vacuo), and ...

dbetavelo

```
double spxprm::dbetavelo
```

(*Returned*) ... vice versa [s/m] (constant, $= 1/c$, always available).

err

```
struct wcserr * spxprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding

```
void * spxprm::padding
```

(An unused variable inserted for alignment purposes only.)

Global variable: const char *spx_errmsg[] - Status return messages Error messages to match the status value returned from each function.

5.13 tabprm Struct Reference

Tabular transformation parameters.

```
#include <tab.h>
```

Data Fields

- int flag
- int M
- int * K
- int * map
- double * crval
- double ** index
- double * coord
- int nc
- int padding
- int * sense
- int * p0
- double * delta
- double * extrema
- struct wcserr * err
- int m_flag
- int m_M
- int m_N
- int set_M
- int * m_K
- int * m_map
- double * m_crval
- double ** m_index
- double ** m_indxs
- double * m_coord

5.13.1 Detailed Description

Tabular transformation parameters.

The **tabprm** struct contains information required to transform tabular coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes while others are for internal use only.

5.13.2 Field Documentation

flag

```
int tabprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following **tabprm** structure members are set or changed:

- tabprm::M (q.v., not normally set by the user),
- tabprm::K (q.v., not normally set by the user),
- tabprm::map,
- tabprm::crval,
- tabprm::index,
- tabprm::coord.

This signals the initialization routine, tabset(), to recompute the returned members of the **tabprm** struct. tabset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag should be set to -1 when tabini() is called for the first time for a particular **tabprm** struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

M

```
int tabprm::M
```

(Given or returned) Number of tabular coordinate axes.

If tabini() is used to initialize the **tabprm** struct (as would normally be the case) then it will set M from the value passed to it as a function argument. The user should not subsequently modify it.

K

```
int * tabprm::K
```

(Given or returned) Pointer to the first element of a vector of length tabprm::M whose elements $(K_1, K_2, ...K_M)$ record the lengths of the axes of the coordinate array and of each indexing vector.

If tabini() is used to initialize the **tabprm** struct (as would normally be the case) then it will set K from the array passed to it as a function argument. The user should not subsequently modify it.

map

```
int * tabprm::map
```

(*Given*) Pointer to the first element of a vector of length tabprm::M that defines the association between axis m in the M-dimensional coordinate array ($1 \leq m \leq M$) and the indices of the intermediate world coordinate and world coordinate arrays, x[] and world[], in the argument lists for tabx2s() and tabs2x().

When x[] and world[] contain the full complement of coordinate elements in image-order, as will usually be the case, then map[m-1] == i-1 for axis i in the N-dimensional image ($1 \leq i \leq N$). In terms of the FITS keywords

map[**PV**i_**3**a - 1] == i - 1.

However, a different association may result if x[], for example, only contains a (relevant) subset of intermediate world coordinate elements. For example, if M == 1 for an image with $N > 1$, it is possible to fill x[] with the relevant coordinate element with nelem set to 1. In this case map[0] = 0 regardless of the value of i.

crval

```
double * tabprm::crval
```

(*Given*) Pointer to the first element of a vector of length tabprm::M whose elements contain the index value for the reference pixel for each of the tabular coordinate axes.

index

```
double ** tabprm::index
```

(*Given*) Pointer to the first element of a vector of length tabprm::M of pointers to vectors of lengths $(K_1, K_2, ...K_M)$ of 0-relative indexes (see tabprm::K).

The address of any or all of these index vectors may be set to zero, i.e.
```
index[m] == 0;
```

this is interpreted as default indexing, i.e.
```
index[m][k] = k;
```

coord

```
double * tabprm::coord
```

(*Given*) Pointer to the first element of the tabular coordinate array, treated as though it were defined as
```
double coord[K_M]...[K_2][K_1][M];
```

(see tabprm::K) i.e. with the M dimension varying fastest so that the M elements of a coordinate vector are stored contiguously in memory.

nc

```
int tabprm::nc
```

(*Returned*) Total number of coordinate vectors in the coordinate array being the product $K_1 K_2 \ldots K_M$(see tabprm::K).

padding

```
int tabprm::padding
```

(An unused variable inserted for alignment purposes only.)

sense

```
int * tabprm::sense
```

(*Returned*) Pointer to the first element of a vector of length tabprm::M whose elements indicate whether the corresponding indexing vector is monotonic increasing (+1), or decreasing (-1).

p0

```
int * tabprm::p0
```

(*Returned*) Pointer to the first element of a vector of length tabprm::M of interpolated indices into the coordinate array such that Υ_m, as defined in Paper III, is equal to (p0[m] + 1) + tabprm::delta[m].

delta

```
double * tabprm::delta
```

(*Returned*) Pointer to the first element of a vector of length tabprm::M of interpolated indices into the coordinate array such that Υ_m, as defined in Paper III, is equal to (tabprm::p0[m] + 1) + delta[m].

extrema

```
double * tabprm::extrema
```

(*Returned*) Pointer to the first element of an array that records the minimum and maximum value of each element of the coordinate vector in each row of the coordinate array, treated as though it were defined as
`double extrema[K_M]...[K_2][2][M]`

(see tabprm::K). The minimum is recorded in the first element of the compressed K_1 dimension, then the maximum. This array is used by the inverse table lookup function, tabs2x(), to speed up table searches.

err

```
struct wcserr * tabprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

m_flag

```
int tabprm::m_flag
```

(For internal use only.)

m_M

```
int tabprm::m_M
```

(For internal use only.)

m_N

```
int tabprm::m_N
```

(For internal use only.)

set_M

```
int tabprm::set_M
```

(For internal use only.)

m_K

```
int tabprm::m_K
```

(For internal use only.)

m_map

```
int tabprm::m_map
```

(For internal use only.)

m_crval

```
int tabprm::m_crval
```

(For internal use only.)

m_index

```
int tabprm::m_index
```

(For internal use only.)

m_indxs

```
int tabprm::m_indxs
```

(For internal use only.)

m_coord

```
int tabprm::m_coord
```

(For internal use only.)

5.14 wcserr Struct Reference

Error message handling.

```
#include <wcserr.h>
```

Data Fields

- int status
- int line_no
- const char * function
- const char * file
- char * msg

5.14.1 Detailed Description

Error message handling.

The **wcserr** struct contains the numeric error code, a textual description of the error, and information about the function, source file, and line number where the error was generated.

5.14.2 Field Documentation

status

```
int wcserr::status
```

Numeric status code associated with the error, the meaning of which depends on the function that generated it. See the documentation for the particular function.

line_no

```
int wcserr::line_no
```

Line number where the error occurred as given by the __LINE__ preprocessor macro.

const char *function Name of the function where the error occurred.

const char *file Name of the source file where the error occurred as given by the __FILE__ preprocessor macro.

function

```
const char* wcserr::function
```

file

```
const char* wcserr::file
```

msg

```
char * wcserr::msg
```

Informative error message.

5.15 wcsprm Struct Reference

5.15.1 Detailed Description

Coordinate transformation parameters.

The **wcsprm** struct contains information required to transform world coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). While the addresses of the arrays themselves may be set by wcsinit() if it (optionally) allocates memory, their contents must be set by the user.

Some parameters that are given are not actually required for transforming coordinates. These are described as "auxiliary"; the struct simply provides a place to store them, though they may be used by wcshdo() in constructing a FITS header from a **wcsprm** struct. Some of the returned values are supplied for informational purposes and others are for internal use only as indicated.

In practice, it is expected that a WCS parser would scan the FITS header to determine the number of coordinate axes. It would then use wcsinit() to allocate memory for arrays in the **wcsprm** struct and set default values. Then as it reread the header and identified each WCS keyrecord it would load the value into the relevant **wcsprm** array element. This is essentially what wcspih() does - refer to the prologue of wcshdr.h. As the final step, wcsset() is invoked, either directly or indirectly, to set the derived members of the **wcsprm** struct. wcsset() strips off trailing blanks in all string members and null-fills the character array.

5.15.2 Field Documentation

flag

```
int wcsprm::flag
```

(Given and returned) This flag must be set to zero whenever any of the following **wcsprm** struct members are set or changed:

- wcsprm::naxis (q.v., not normally set by the user),
- wcsprm::crpix,
- wcsprm::pc,
- wcsprm::cdelt,
- wcsprm::crval,
- wcsprm::cunit,
- wcsprm::ctype,
- wcsprm::lonpole,
- wcsprm::latpole,
- wcsprm::restfrq,
- wcsprm::restwav,
- wcsprm::npv,
- wcsprm::pv,
- wcsprm::nps,
- wcsprm::ps,
- wcsprm::cd,
- wcsprm::crota,
- wcsprm::altlin,
- wcsprm::ntab,
- wcsprm::nwtb,
- wcsprm::tab,
- wcsprm::wtb.

This signals the initialization routine, wcsset(), to recompute the returned members of the linprm, celprm, spcprm, and tabprm structs. wcsset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag should be set to -1 when wcsinit() is called for the first time for a particular **wcsprm** struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

naxis

```
int wcsprm::naxis
```

(Given or returned) Number of pixel and world coordinate elements.

If wcsinit() is used to initialize the linprm struct (as would normally be the case) then it will set naxis from the value passed to it as a function argument. The user should not subsequently modify it.

crpix

```
double * wcsprm::crpix
```

(*Given*) Address of the first element of an array of double containing the coordinate reference pixel, **CRPIX**ja.

pc

```
double * wcsprm::pc
```

(*Given*) Address of the first element of the **PC**i_ja (pixel coordinate) transformation matrix. The expected order is

```
struct wcsprm wcs;
wcs.pc = {PC1_1, PC1_2, PC2_1, PC2_2};
```

This may be constructed conveniently from a 2-D array via

```
double m[2][2] = {{PC1_1, PC1_2},
                  {PC2_1, PC2_2}};
```

which is equivalent to

```
double m[2][2];
m[0][0] = PC1_1;
m[0][1] = PC1_2;
m[1][0] = PC2_1;
m[1][1] = PC2_2;
```

The storage order for this 2-D array is the same as for the 1-D array, whence

```
wcs.pc = *m;
```

would be legitimate.

cdelt

```
double * wcsprm::cdelt
```

(*Given*) Address of the first element of an array of double containing the coordinate increments, **CDELT**ia.

crval

```
double * wcsprm::crval
```

(*Given*) Address of the first element of an array of double containing the coordinate reference values, **CRVAL**ia.

cunit

`wcsprm::cunit`

(*Given*) Address of the first element of an array of char[72] containing the **CUNIT**ia keyvalues which define the units of measurement of the **CRVAL**ia, **CDELT**ia, and **CD**i_ja keywords.

As **CUNIT**ia is an optional header keyword, cunit[][72] may be left blank but otherwise is expected to contain a standard units specification as defined by WCS Paper I. Utility function wcsutrn(), described in wcsunits.h, is available to translate commonly used non-standard units specifications but this must be done as a separate step before invoking wcsset().

For celestial axes, if cunit[][72] is not blank, wcsset() uses wcsunits() to parse it and scale cdelt[], crval[], and cd[][*] to degrees. It then resets cunit[][72] to "deg".

For spectral axes, if cunit[][72] is not blank, wcsset() uses wcsunits() to parse it and scale cdelt[], crval[], and cd[][*] to SI units. It then resets cunit[][72] accordingly.

wcsset() ignores cunit[][72] for other coordinate types; cunit[][72] may be used to label coordinate values.

These variables accomodate the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

ctype

`wcsprm::ctype`

(*Given*) Address of the first element of an array of char[72] containing the coordinate axis types, **CTYPE**ia.

The ctype[][72] keyword values must be in upper case and there must be zero or one pair of matched celestial axis types, and zero or one spectral axis. The ctype[][72] strings should be padded with blanks on the right and null-terminated so that they are at least eight characters in length.

These variables accomodate the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

lonpole

`double wcsprm::lonpole`

(Given and returned) The native longitude of the celestial pole, $\phi_{\rm p}$, given by **LONPOLE**a [deg] or by **PVi_2a** [deg] attached to the longitude axis which takes precedence if defined, and ...

latpole

`double wcsprm::latpole`

(Given and returned) ... the native latitude of the celestial pole, $\theta_{\rm p}$, given by **LATPOLE**a [deg] or by **PVi_3a** [deg] attached to the longitude axis which takes precedence if defined.

lonpole and latpole may be left to default to values set by wcsinit() (see celprm::ref), but in any case they will be reset by wcsset() to the values actually used. Note therefore that if the **wcsprm** struct is reused without resetting them, whether directly or via wcsinit(), they will no longer have their default values.

restfrq

```
double wcsprm::restfrq
```

(*Given*) The rest frequency [Hz], and/or ...

restwav

```
double wcsprm::restwav
```

(*Given*) ... the rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero.

npv

```
int wcsprm::npv
```

(*Given*) The number of entries in the wcsprm::pv[] array.

npvmax

```
int wcsprm::npvmax
```

(Given or returned) The length of the wcsprm::pv[] array.

npvmax will be set by wcsinit() if it allocates memory for wcsprm::pv[], otherwise it must be set by the user. See also wcsnpv().

pv

```
struct pvcard * wcsprm::pv
```

(*Given*) Address of the first element of an array of length npvmax of pvcard structs.

As a FITS header parser encounters each **PV**i_ma keyword it should load it into a pvcard struct in the array and increment npv. wcsset() interprets these as required.

Note that, if they were not given, wcsset() resets the entries for **PVi_1a**, **PVi_2a**, **PVi_3a**, and **PVi_4a** for longitude axis **i** to match phi_0 and theta_0 (the native longitude and latitude of the reference point), **LONPOLE**a and **LATPOLE**a respectively.

nps

```
int wcsprm::nps
```

(*Given*) The number of entries in the wcsprm::ps[] array.

npsmax

```
int wcsprm::npsmax
```

(Given or returned) The length of the wcsprm::ps[] array.

npsmax will be set by wcsinit() if it allocates memory for wcsprm::ps[], otherwise it must be set by the user. See also wcsnps().

ps

```
struct pscard * wcsprm::ps
```

(*Given*) Address of the first element of an array of length npsmax of pscard structs.

As a FITS header parser encounters each **PS**i_ma keyword it should load it into a pscard struct in the array and increment nps. wcsset() interprets these as required (currently no **PS**i_ma keyvalues are recognized).

cd

```
double * wcsprm::cd
```

(*Given*) For historical compatibility, the **wcsprm** struct supports two alternate specifications of the linear transformation matrix, those associated with the **CD**i_ja keywords, and ...

crota

```
double * wcsprm::crota
```

(*Given*) ... those associated with the **CROTA**i keywords. Although these may not formally co-exist with **PC**i_ja, the approach taken here is simply to ignore them if given in conjunction with **PC**i_ja.

altlin

```
int wcsprm::altlin
```

(*Given*) altlin is a bit flag that denotes which of the **PC**i_ja, **CD**i_ja and **CROTA**i keywords are present in the header:

- Bit 0: **PC**i_ja is present.
- Bit 1: **CD**i_ja is present.

  Matrix elements in the IRAF convention are equivalent to the product **CD**i_ja = **CDELT**ia * **PC**i_ja, but the defaults differ from that of the **PC**i_ja matrix. If one or more **CD**i_ja keywords are present then all unspecified **CD**i_ja default to zero. If no **CD**i_ja (or **CROTA**i) keywords are present, then the header is assumed to be in **PC**i_ja form whether or not any **PC**i_ja keywords are present since this results in an interpretation of **CDELT**ia consistent with the original FITS specification.

  While **CD**i_ja may not formally co-exist with **PC**i_ja, it may co-exist with **CDELT**ia and **CROTA**i which are to be ignored.

- Bit 2: **CROTA**i is present.

  In the AIPS convention, **CROTA**i may only be associated with the latitude axis of a celestial axis pair. It specifies a rotation in the image plane that is applied AFTER the **CDELT**ia; any other **CROTA**i keywords are ignored.

  CROTAi may not formally co-exist with **PC**i_ja.

  CROTAi and **CDELT**ia may formally co-exist with **CD**i_ja but if so are to be ignored.

- Bit 3: **PC**i_ja + **CDELT**ia was derived from **CD**i_ja by wcspcx().

  This bit is set by wcspcx() when it derives **PC**i_ja and **CDELT**ia from **CD**i_ja via an orthonormal decomposition. In particular, it signals wcsset() not to replace **PC**i_ja by a copy of **CD**i_ja with **CDELT**ia set to unity.

CDi_ja and **CROTA**i keywords, if found, are to be stored in the wcsprm::cd and wcsprm::crota arrays which are dimensioned similarly to wcsprm::pc and wcsprm::cdelt. FITS header parsers should use the following procedure:

- Whenever a **PC**i_ja keyword is encountered:
  ```
  altlin |= 1;
  ```
- Whenever a **CD**i_ja keyword is encountered:
  ```
  altlin |= 2;
  ```
- Whenever a **CROTA**i keyword is encountered:
  ```
  altlin |= 4;
  ```

If none of these bits are set the **PC**i_ja representation results, i.e. wcsprm::pc and wcsprm::cdelt will be used as given.

These alternate specifications of the linear transformation matrix are translated immediately to **PC**i_ja by wcsset() and are invisible to the lower-level WCSLIB routines. In particular, unless bit 3 is also set, wcsset() resets wcsprm::cdelt to unity if **CD**i_ja is present (and no **PC**i_ja).

If **CROTA**i are present but none is associated with the latitude axis (and no **PC**i_ja or **CD**i_ja), then wcsset() reverts to a unity **PC**i_ja matrix.

velref

```
int wcsprm::velref
```

(*Given*) AIPS velocity code **VELREF**, refer to spcaips().

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::velref is changed.

alt

```
char wcsprm::alt
```

(Given, auxiliary) Character code for alternate coordinate descriptions (i.e. the '**a**' in keyword names such as **CTYPE**ia). This is blank for the primary coordinate description, or one of the 26 upper-case letters, A-Z.

An array of four characters is provided for alignment purposes, only the first is used.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::alt is changed.

colnum

```
int wcsprm::colnum
```

(Given, auxiliary) Where the coordinate representation is associated with an image-array column in a FITS binary table, this variable may be used to record the relevant column number.

It should be set to zero for an image header or pixel list.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::colnum is changed.

colax

```
int * wcsprm::colax
```

(Given, auxiliary) Address of the first element of an array of int recording the column numbers for each axis in a pixel list.

The array elements should be set to zero for an image header or image array in a binary table.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::colax is changed.

cname

```
wcsprm::cname
```

(Given, auxiliary) The address of the first element of an array of char[72] containing the coordinate axis names, **CNAME**ia.

These variables accomodate the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::cname is changed.

crder

```
double * wcsprm::crder
```

(Given, auxiliary) Address of the first element of an array of double recording the random error in the coordinate value, **CRDER**ia.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::crder is changed.

csyer

```
double * wcsprm::csyer
```

(Given, auxiliary) Address of the first element of an array of double recording the systematic error in the coordinate value, **CSYER**ia.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::csyer is changed.

czphs

```
double * wcsprm::czphs
```

(Given, auxiliary) Address of the first element of an array of double recording the time at the zero point of a phase axis, CZPHSia.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::czphs is changed.

cperi

```
double * wcsprm::cperi
```

(Given, auxiliary) Address of the first element of an array of double recording the period of a phase axis, CPERIia.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::cperi is changed.

wcsname

```
char wcsprm::wcsname
```

(Given, auxiliary) The name given to the coordinate representation, **WCSNAME**a. This variable accomodates the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::wcsname is changed.

timesys

```
char wcsprm::timesys
```

(Given, auxiliary) **TIMESYS** keyvalue, being the time scale (UTC, TAI, etc.) in which all other time-related auxiliary header values are recorded. Also defines the time scale for an image axis with **CTYPE**ia set to 'TIME'.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timesys is changed.

trefpos

```
char wcsprm::trefpos
```

(Given, auxiliary) **TREFPOS** keyvalue, being the location in space where the recorded time is valid.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::trefpos is changed.

trefdir

```
char wcsprm::trefdir
```

(Given, auxiliary) **TREFDIR** keyvalue, being the reference direction used in calculating a pathlength delay.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::trefdir is changed.

plephem

```
char wcsprm::plephem
```

(Given, auxiliary) **PLEPHEM** keyvalue, being the Solar System ephemeris used for calculating a pathlength delay.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::plephem is changed.

timeunit

```
char wcsprm::timeunit
```

(Given, auxiliary) **TIMEUNIT** keyvalue, being the time units in which the following header values are expressed: **TSTART**, **TSTOP**, **TIMEOFFS**, **TIMSYER**, **TIMRDER**, **TIMEDEL**. It also provides the default value for **CUNIT**`ia` for time axes.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timeunit is changed.

dateref

```
char wcsprm::dateref
```

(Given, auxiliary) **DATEREF** keyvalue, being the date of a reference epoch relative to which other time measurements refer.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::dateref is changed.

mjdref

```
double wcsprm::mjdref
```

(Given, auxiliary) **MJDREF** keyvalue, equivalent to **DATEREF** expressed as a Modified Julian Date (MJD = JD - 2400000.5). The value is given as the sum of the two-element vector, allowing increased precision.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::mjdref is changed.

timeoffs

```
double wcsprm::timeoffs
```

(Given, auxiliary) **TIMEOFFS** keyvalue, being a time offset, which may be used, for example, to provide a uniform clock correction for times referenced to **DATEREF**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timeoffs is changed.

dateobs

```
char wcsprm::dateobs
```

(Given, auxiliary) **DATE-OBS** keyvalue, being the date at the start of the observation unless otherwise explained in the **DATE-OBS** keycomment, in ISO format, *yyyy-mm-dd***T***hh:mm:ss*.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::dateobs is changed.

datebeg

```
char wcsprm::datebeg
```

(Given, auxiliary) **DATE-BEG** keyvalue, being the date at the start of the observation in ISO format, *yyyy-mm-dd***T***hh:mm:ss*.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::datebeg is changed.

dateavg

```
char wcsprm::dateavg
```

(Given, auxiliary) **DATE-AVG** keyvalue, being the date at a representative mid-point of the observation in ISO format, *yyyy-mm-dd***T***hh:mm:ss*.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::dateavg is changed.

dateend

```
char wcsprm::dateend
```

(Given, auxiliary) **DATE-END** keyvalue, baing the date at the end of the observation in ISO format, *yyyy-mm-dd***T***hh:mm:ss*.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::dateend is changed.

mjdobs

```
double wcsprm::mjdobs
```

(Given, auxiliary) **MJD-OBS** keyvalue, equivalent to **DATE-OBS** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::mjdobs is changed.

mjdbeg

```
double wcsprm::mjdbeg
```

(Given, auxiliary) **MJD-BEG** keyvalue, equivalent to **DATE-BEG** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::mjdbeg is changed.

mjdavg

```
double wcsprm::mjdavg
```

(Given, auxiliary) **MJD-AVG** keyvalue, equivalent to **DATE-AVG** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::mjdavg is changed.

mjdend

```
double wcsprm::mjdend
```

(Given, auxiliary) **MJD-END** keyvalue, equivalent to **DATE-END** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::mjdend is changed.

jepoch

```
double wcsprm::jepoch
```

(Given, auxiliary) J**EPOCH** keyvalue, equivalent to **DATE-OBS** expressed as a Julian epoch.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::jepoch is changed.

bepoch

```
double wcsprm::bepoch
```

(Given, auxiliary) B**EPOCH** keyvalue, equivalent to **DATE-OBS** expressed as a Besselian epoch

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::bepoch is changed.

tstart

```
double wcsprm::tstart
```

(Given, auxiliary) **TSTART** keyvalue, equivalent to **DATE-BEG** expressed as a time in units of **TIMEUNIT** relative to **DATEREF**+**TIMEOFFS**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::tstart is changed.

tstop

```
double wcsprm::tstop
```

(Given, auxiliary) **TSTOP** keyvalue, equivalent to **DATE-END** expressed as a time in units of **TIMEUNIT** relative to **DATEREF**+**TIMEOFFS**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::tstop is changed.

xposure

```
double wcsprm::xposure
```

(Given, auxiliary) **XPOSURE** keyvalue, being the effective exposure time in units of **TIMEUNIT**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::xposure is changed.

telapse

```
double wcsprm::telapse
```

(Given, auxiliary) **TELAPSE** keyvalue, equivalent to the elapsed time between **DATE-BEG** and **DATE-END**, in units of **TIMEUNIT**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::telapse is changed.

timsyer

```
double wcsprm::timsyer
```

(Given, auxiliary) **TIMSYER** keyvalue, being the absolute error of the time values, in units of **TIMEUNIT**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timsyer is changed.

timrder

```
double wcsprm::timrder
```

(Given, auxiliary) **TIMRDER** keyvalue, being the accuracy of time stamps relative to each other, in units of **TIMEUNIT**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timrder is changed.

timedel

```
double wcsprm::timedel
```

(Given, auxiliary) **TIMEDEL** keyvalue, being the resolution of the time stamps.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timedel is changed.

timepixr

```
double wcsprm::timepixr
```

(Given, auxiliary) **TIMEPIXR** keyvalue, being the relative position of the time stamps in binned time intervals, a value between 0.0 and 1.0.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timepixr is changed.

obsgeo

```
double wcsprm::obsgeo
```

(Given, auxiliary) Location of the observer in a standard terrestrial reference frame. The first three give ITRS Cartesian coordinates **OBSGEO-X** [m], **OBSGEO-Y** [m], **OBSGEO-Z** [m], and the second three give **OBSGEO-L** [deg], **OBSGEO-B** [deg], **OBSGEO-H** [m], which are related through a standard transformation.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::obsgeo is changed.

obsorbit

```
char wcsprm::obsorbit
```

(Given, auxiliary) **OBSORBIT** keyvalue, being the URI, URL, or name of an orbit ephemeris file giving spacecraft coordinates relating to **TREFPOS**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::obsorbit is changed.

radesys

```
char wcsprm::radesys
```

(Given, auxiliary) The equatorial or ecliptic coordinate system type, **RADESYS**a.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::radesys is changed.

equinox

```
double wcsprm::equinox
```

(Given, auxiliary) The equinox associated with dynamical equatorial or ecliptic coordinate systems, **EQUINOX**a (or **EPOCH** in older headers). Not applicable to ICRS equatorial or ecliptic coordinates.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::equinox is changed.

specsys

```
char wcsprm::specsys
```

(Given, auxiliary) Spectral reference frame (standard of rest), **SPECSYS**a.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::specsys is changed.

ssysobs

```
char wcsprm::ssysobs
```

(Given, auxiliary) The spectral reference frame in which there is no differential variation in the spectral coordinate across the field-of-view, **SSYSOBS**a.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::ssysobs is changed.

velosys

```
double wcsprm::velosys
```

(Given, auxiliary) The relative radial velocity [m/s] between the observer and the selected standard of rest in the direction of the celestial reference coordinate, **VELOSYS**a.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::velosys is changed.

zsource

```
double wcsprm::zsource
```

(Given, auxiliary) The redshift, **ZSOURCE**a, of the source.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::zsource is changed.

ssyssrc

```
char wcsprm::ssyssrc
```

(Given, auxiliary) The spectral reference frame (standard of rest), **SSYSSRC**a, in which wcsprm::zsource was measured.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::ssyssrc is changed.

velangl

```
double wcsprm::velangl
```

(Given, auxiliary) The angle [deg] that should be used to decompose an observed velocity into radial and transverse components.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::velangl is changed.

aux

```
struct auxprm * wcsprm::aux
```

(Given, auxiliary) This struct holds auxiliary coordinate system information of a specialist nature. While these parameters may be widely recognized within particular fields of astronomy, they differ from the above auxiliary parameters in not being defined by any of the FITS WCS standards. Collecting them together in a separate struct that is allocated only when required helps to control bloat in the size of the **wcsprm** struct.

ntab

```
int wcsprm::ntab
```

(*Given*) See wcsprm::tab.

nwtb

```
int wcsprm::nwtb
```

(*Given*) See wcsprm::wtb.

tab

```
struct tabprm * wcsprm::tab
```

(*Given*) Address of the first element of an array of ntab tabprm structs for which memory has been allocated. These are used to store tabular transformation parameters.

Although technically wcsprm::ntab and tab are "given", they will normally be set by invoking wcstab(), whether directly or indirectly.

The tabprm structs contain some members that must be supplied and others that are derived. The information to be supplied comes primarily from arrays stored in one or more FITS binary table extensions. These arrays, referred to here as "wcstab arrays", are themselves located by parameters stored in the FITS image header.

wtb

```
struct wtbarr * wcsprm::wtb
```

(*Given*) Address of the first element of an array of nwtb wtbarr structs for which memory has been allocated. These are used in extracting wcstab arrays from a FITS binary table.

Although technically wcsprm::nwtb and wtb are "given", they will normally be set by invoking wcstab(), whether directly or indirectly.

lngtyp

```
char wcsprm::lngtyp
```

(*Returned*) Four-character WCS celestial longitude and ...

lattyp

```
char wcsprm::lattyp
```

(*Returned*) ... latitude axis types. e.g. "RA", "DEC", "GLON", "GLAT", etc. extracted from '**RA--**', '**DEC--**', '**GLON**', '**GLAT**', etc. in the first four characters of **CTYPE**ia but with trailing dashes removed. (Declared as char[8] for alignment reasons.)

lng

```
int wcsprm::lng
```

(*Returned*) Index for the longitude coordinate, and ...

lat

```
int wcsprm::lat
```

(*Returned*) ... index for the latitude coordinate, and ...

spec

```
int wcsprm::spec
```

(*Returned*) ... index for the spectral coordinate, and ...

time

```
int wcsprm::time
```

(*Returned*) ... index for the time coordinate in the imgcrd[][] and world[][] arrays in the API of wcsp2s(), wcss2p() and wcsmix().

These may also serve as indices into the pixcrd[][] array provided that the **PC**`i_ja` matrix does not transpose axes.

cubeface

```
int wcsprm::cubeface
```

(*Returned*) Index into the pixcrd[][] array for the **CUBEFACE** axis. This is used for quadcube projections where the cube faces are stored on a separate axis (see wcs.h).

dummy

```
int wcsprm::dummy
```

types

```
int * wcsprm::types
```

(*Returned*) Address of the first element of an array of int containing a four-digit type code for each axis.

- First digit (i.e. 1000s):
  - 0: Non-specific coordinate type.
  - 1: Stokes coordinate.
  - 2: Celestial coordinate (including **CUBEFACE**).
  - 3: Spectral coordinate.
  - 4: Time coordinate.
- Second digit (i.e. 100s):
  - 0: Linear axis.
  - 1: Quantized axis (**STOKES**, **CUBEFACE**).
  - 2: Non-linear celestial axis.
  - 3: Non-linear spectral axis.
  - 4: Logarithmic axis.
  - 5: Tabular axis.

- Third digit (i.e. 10s):
  - 0: Group number, e.g. lookup table number, being an index into the tabprm array (see above).
- The fourth digit is used as a qualifier depending on the axis type.
  - For celestial axes:
    - 0: Longitude coordinate.
    - 1: Latitude coordinate.
    - 2: **CUBEFACE** number.
  - For lookup tables: the axis number in a multidimensional table.

CTYPE`ia` in "4-3" form with unrecognized algorithm code will have its type set to -1 and generate an error.

lin

```
struct linprm wcsprm::lin
```

(*Returned*) Linear transformation parameters (usage is described in the prologue to lin.h).

cel

```
struct celprm wcsprm::cel
```

(*Returned*) Celestial transformation parameters (usage is described in the prologue to cel.h).

spc

```
struct spcprm wcsprm::spc
```

(*Returned*) Spectral transformation parameters (usage is described in the prologue to spc.h).

err

```
struct wcserr * wcsprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

m_flag

```
int wcsprm::m_flag
```

(For internal use only.)

m_naxis

```
int wcsprm::m_naxis
```

(For internal use only.)

m_crpix

```
double * wcsprm::m_crpix
```

(For internal use only.)

m_pc

```
double * wcsprm::m_pc
```

(For internal use only.)

m_cdelt

```
double * wcsprm::m_cdelt
```

(For internal use only.)

m_crval

```
double * wcsprm::m_crval
```

(For internal use only.)

m_cunit

```
wcsprm::m_cunit
```

(For internal use only.)

m_ctype

```
wcsprm::m_ctype
```

(For internal use only.)

m_pv

```
struct pvcard * wcsprm::m_pv
```

(For internal use only.)

m_ps

```
struct pscard * wcsprm::m_ps
```

(For internal use only.)

m_cd

```
double * wcsprm::m_cd
```

(For internal use only.)

m_crota

```
double * wcsprm::m_crota
```

(For internal use only.)

m_colax

```
int * wcsprm::m_colax
```

(For internal use only.)

m_cname

```
wcsprm::m_cname
```

(For internal use only.)

m_crder

```
double * wcsprm::m_crder
```

(For internal use only.)

m_csyer

```
double * wcsprm::m_csyer
```

(For internal use only.)

m_czphs

```
double * wcsprm::m_czphs
```

(For internal use only.)

m_cperi

```
double * wcsprm::m_cperi
```

(For internal use only.)

m_aux

```
struct auxprm* wcsprm::m_aux
```

m_tab

```
struct tabprm * wcsprm::m_tab
```

(For internal use only.)

m_wtb

```
struct wtbarr * wcsprm::m_wtb
```

(For internal use only.)

5.16 wtbarr Struct Reference

Extraction of coordinate lookup tables from BINTABLE.

```
#include <getwcstab.h>
```

Data Fields

- int i
- int m
- int kind
- char extnam [72]
- int extver
- int extlev
- char ttype [72]
- long row
- int ndim
- int * dimlen
- double ** arrayp

5.16.1 Detailed Description

Extraction of coordinate lookup tables from BINTABLE.

Function wcstab(), which is invoked automatically by wcspih(), sets up an array of **wtbarr** structs to assist in extracting coordinate lookup tables from a binary table extension (BINTABLE) and copying them into the tabprm structs stored in wcsprm. Refer to the usage notes for wcspih() and wcstab() in wcshdr.h, and also the prologue to tab.h.

For C++ usage, because of a name space conflict with the **wtbarr** typedef defined in CFITSIO header fitsio.h, the **wtbarr** struct is renamed to **wtbarr_s** by preprocessor macro substitution with scope limited to **wtbarr.h** itself, and similarly in wcs.h.

5.16.2 Field Documentation

i

```
int wtbarr::i
```

(*Given*) Image axis number.

m

```
int wtbarr::m
```

(*Given*) wcstab array axis number for index vectors.

kind

```
int wtbarr::kind
```

(*Given*) Character identifying the wcstab array type:

- c: coordinate array,
- i: index vector.

extnam

```
char wtbarr::extnam
```

(*Given*) **EXTNAME** identifying the binary table extension.

extver

```
int wtbarr::extver
```

(*Given*) **EXTVER** identifying the binary table extension.

extlev

```
int wtbarr::extlev
```

(*Given*) **EXTLEV** identifying the binary table extension.

ttype

```
char wtbarr::ttype
```

(*Given*) **TTYPE**n identifying the column of the binary table that contains the wcstab array.

row

```
long wtbarr::row
```

(*Given*) Table row number.

ndim

```
int wtbarr::ndim
```

(*Given*) Expected dimensionality of the wcstab array.

dimlen

```
int * wtbarr::dimlen
```

(*Given*) Address of the first element of an array of int of length ndim into which the wcstab array axis lengths are to be written.

arrayp

```
double ** wtbarr::arrayp
```

(*Given*) Pointer to an array of double which is to be allocated by the user and into which the wcstab array is to be written.

6 File Documentation

6.1 cel.h File Reference

```
#include "prj.h"
```

Data Structures

- struct celprm

  Celestial transformation parameters.

Macros

- #define CELLEN (sizeof(struct celprm)/sizeof(int))

  Size of the celprm struct in int units.
- #define celini_errmsg cel_errmsg

  Deprecated.
- #define celprt_errmsg cel_errmsg

Functions

- int celini (struct celprm *cel)

  Default constructor for the celprm struct.
- int celfree (struct celprm *cel)

  Destructor for the celprm struct.
- int celsize (const struct celprm *cel, int sizes[2])

  Compute the size of a celprm struct.
- int celprt (const struct celprm *cel)

  Print routine for the celprm struct.
- int celperr (const struct celprm *cel, const char *prefix)

  Print error messages from a celprm struct.
- int celset (struct celprm *cel)

  Setup routine for the celprm struct.
- int celx2s (struct celprm *cel, int nx, int ny, int sxy, int sll, const double x[ ], const double y[ ], double phi[ ], double theta[ ], double lng[ ], double lat[ ], int stat[ ])

  Pixel-to-world celestial transformation.
- int cels2x (struct celprm *cel, int nlng, int nlat, int sll, int sxy, const double lng[ ], const double lat[ ], double phi[ ], double theta[ ], double x[ ], double y[ ], int stat[ ])

  World-to-pixel celestial transformation.

Variables

- const char * cel_errmsg [ ]

6.1.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with celestial coordinates, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
```

These routines define methods to be used for computing celestial world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa. They are based on the celprm struct which contains all information needed for the computations. This struct contains some elements that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Routine celini() is provided to initialize the celprm struct with default values, celfree() reclaims any memory that may have been allocated to store an error message, celsize() computes its total size including allocated memory, and celprt() prints its contents.

celperr() prints the error message(s), if any, stored in a celprm struct and the prjprm struct that it contains.

A setup routine, celset(), computes intermediate values in the celprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by celset() but it need not be called explicitly - refer to the explanation of celprm::flag.

celx2s() and cels2x() implement the WCS celestial coordinate transformations. In fact, they are high level driver routines for the lower level spherical coordinate rotation and projection routines described in sph.h and prj.h.

6.1.2 Macro Definition Documentation

CELLEN

```
#define CELLEN (sizeof(struct celprm)/sizeof(int))
```

Size of the celprm struct in *int* units.

Size of the celprm struct in *int* units, used by the Fortran wrappers.

celini_errmsg

```
#define celini_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

celprt_errmsg

```
#define celprt_errmsg cel_errmsg
```

cels2x_errmsg

```
#define cels2x_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

6.1.3 Enumeration Type Documentation

cel_errmsg_enum

```
enum cel_errmsg_enum
```

Enumerator

CELERR_SUCCESS	
CELERR_NULL_POINTER	
CELERR_BAD_PARAM	
CELERR_BAD_COORD_TRANS	
CELERR_ILL_COORD_TRANS	
CELERR_BAD_PIX	
CELERR_BAD_WORLD	

6.1.4 Function Documentation

celini()

```
int celini (
            struct celprm * cel )
```

Default constructor for the celprm struct.

celini() sets all members of a celprm struct to default values. It should be used to initialize every celprm struct.

PLEASE NOTE: If the celprm struct has already been initialized, then before reinitializing, it celfree() should be used to free any memory that may have been allocated to store an error message. A memory leak may otherwise result.

Parameters

out	*cel*	Celestial transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celfree()

```
int celfree (
            struct celprm * cel )
```

Destructor for the celprm struct.

celfree() frees any memory that may have been allocated to store an error message in the celprm struct.

Parameters

in	*cel*	Celestial transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celsize()

```
int celsize (
            const struct celprm * cel,
            int sizes[2] )
```

Compute the size of a celprm struct.

celsize() computes the full size of a celprm struct, including allocated memory.

Parameters

in	*cel*	Celestial transformation parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct celprm). The second element is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct, celprm::err. It is not an error for the struct not to have been set up via celset().

Returns

Status return value:

- 0: Success.

celprt()

```
int celprt (
            const struct celprm * cel )
```

Print routine for the celprm struct.

celprt() prints the contents of a celprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*cel*	Celestial transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celperr()

```
int celperr (
            const struct celprm * cel,
            const char * prefix )
```

Print error messages from a celprm struct.

celperr() prints the error message(s), if any, stored in a celprm struct and the prjprm struct that it contains. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*cel*	Coordinate transformation parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celset()

```
int celset (
            struct celprm * cel )
```

Setup routine for the celprm struct.

celset() sets up a celprm struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by celx2s() and cels2x() if celprm::flag is anything other than a predefined magic value.

Parameters

in,out	*cel*	Celestial transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.
- 2: Invalid projection parameters.
- 3: Invalid coordinate transformation parameters.
- 4: Ill-conditioned coordinate transformation parameters.

For returns $>$ 1, a detailed error message is set in celprm::err if enabled, see wcserr_enable().

celx2s()

```
int celx2s (
            struct celprm * cel,
            int nx,
            int ny,
            int sxy,
            int sll,
            const double x[],
```

```
            const double y[],
            double phi[],
            double theta[],
            double lng[],
            double lat[],
            int stat[] )
```

Pixel-to-world celestial transformation.

celx2s() transforms (x, y) coordinates in the plane of projection to celestial coordinates (α, δ).

Parameters

in,out	*cel*	Celestial transformation parameters.
in	*nx,ny*	Vector lengths.
in	*sxy,sll*	Vector strides.
in	*x,y*	Projected coordinates in pseudo "degrees".
out	*phi,theta*	Longitude and latitude (ϕ, θ) in the native coordinate system of the projection [deg].
out	*lng,lat*	Celestial longitude and latitude (α, δ) of the projected point [deg].
out	*stat*	Status return value for each vector element: • 0: Success. • 1: Invalid value of (x, y).

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.
- 2: Invalid projection parameters.
- 3: Invalid coordinate transformation parameters.
- 4: Ill-conditioned coordinate transformation parameters.
- 5: One or more of the (x, y) coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in celprm::err if enabled, see wcserr_enable().

cels2x()

```
int cels2x (
            struct celprm * cel,
            int nlng,
            int nlat,
            int sll,
            int sxy,
            const double lng[],
            const double lat[],
            double phi[],
            double theta[],
            double x[],
```

```
            double y[],
            int stat[] )
```

World-to-pixel celestial transformation.

cels2x() transforms celestial coordinates (α, δ) to (x, y) coordinates in the plane of projection.

Parameters

in,out	*cel*	Celestial transformation parameters.
in	*nlng,nlat*	Vector lengths.
in	*sll,sxy*	Vector strides.
in	*lng,lat*	Celestial longitude and latitude (α, δ) of the projected point [deg].
out	*phi,theta*	Longitude and latitude (ϕ, θ) in the native coordinate system of the projection [deg].
out	*x,y*	Projected coordinates in pseudo "degrees".
out	*stat*	Status return value for each vector element: • 0: Success. • 1: Invalid value of (α, δ).

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.
- 2: Invalid projection parameters.
- 3: Invalid coordinate transformation parameters.
- 4: Ill-conditioned coordinate transformation parameters.
- 6: One or more of the (α, δ) coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in celprm::err if enabled, see wcserr_enable().

6.1.5 Variable Documentation

cel_errmsg

```
const char* cel_errmsg[]  [extern]
```

00023 *===========================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the cel routines
00031 * ---------------------------
00032 * Routines in this suite implement the part of the FITS World Coordinate
00033 * System (WCS) standard that deals with celestial coordinates, as described in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 =
00038 =   "Representations of celestial coordinates in FITS",
00039 =   Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
00040 *
00041 * These routines define methods to be used for computing celestial world
00042 * coordinates from intermediate world coordinates (a linear transformation
00043 * of image pixel coordinates), and vice versa.  They are based on the celprm
00044 * struct which contains all information needed for the computations.  This
00045 * struct contains some elements that must be set by the user, and others that
00046 * are maintained by these routines, somewhat like a C++ class but with no
00047 * encapsulation.
00048 *
00049 * Routine celini() is provided to initialize the celprm struct with default
00050 * values, celfree() reclaims any memory that may have been allocated to store
00051 * an error message, celsize() computes its total size including allocated
00052 * memory, and celprt() prints its contents.
00053 *
00054 * celperr() prints the error message(s), if any, stored in a celprm struct and
00055 * the prjprm struct that it contains.
00056 *
00057 * A setup routine, celset(), computes intermediate values in the celprm struct
00058 * from parameters in it that were supplied by the user.  The struct always
00059 * needs to be set up by celset() but it need not be called explicitly - refer
00060 * to the explanation of celprm::flag.
00061 *
00062 * celx2s() and cels2x() implement the WCS celestial coordinate
00063 * transformations.  In fact, they are high level driver routines for the lower
00064 * level spherical coordinate rotation and projection routines described in
00065 * sph.h and prj.h.
00066 *
00067 *
00068 * celini() - Default constructor for the celprm struct
00069 * ----------------------------------------------------
00070 * celini() sets all members of a celprm struct to default values.  It should
00071 * be used to initialize every celprm struct.
00072 *
00073 * PLEASE NOTE: If the celprm struct has already been initialized, then before
00074 * reinitializing, it celfree() should be used to free any memory that may have
00075 * been allocated to store an error message.  A memory leak may otherwise
00076 * result.
00077 *
00078 * Returned:
00079 *   cel       struct celprm*
00080 *                       Celestial transformation parameters.
00081 *
00082 * Function return value:
00083 *             int       Status return value:
00084 *                         0: Success.
00085 *                         1: Null celprm pointer passed.
00086 *
00087 *
00088 * celfree() - Destructor for the celprm struct
00089 * --------------------------------------------
00090 * celfree() frees any memory that may have been allocated to store an error
00091 * message in the celprm struct.
00092 *
00093 * Given:
00094 *   cel       struct celprm*
00095 *                       Celestial transformation parameters.
00096 *
00097 * Function return value:
00098 *             int       Status return value:
00099 *                         0: Success.
00100 *                         1: Null celprm pointer passed.
00101 *
00102 *
00103 * celsize() - Compute the size of a celprm struct
00104 * ----------------------------------------------
00105 * celsize() computes the full size of a celprm struct, including allocated
00106 * memory.
00107 *
00108 * Given:
00109 *   cel       const struct celprm*
```

```
00110 *                       Celestial transformation parameters.
00111 *
00112 *                       If NULL, the base size of the struct and the allocated
00113 *                       size are both set to zero.
00114 *
00115 * Returned:
00116 *   sizes     int[2]    The first element is the base size of the struct as
00117 *                       returned by sizeof(struct celprm).  The second element
00118 *                       is the total allocated size, in bytes.  This figure
00119 *                       includes memory allocated for the constituent struct,
00120 *                       celprm::err.
00121 *
00122 *                       It is not an error for the struct not to have been set
00123 *                       up via celset().
00124 *
00125 * Function return value:
00126 *             int       Status return value:
00127 *                         0: Success.
00128 *
00129 *
00130 * celprt() - Print routine for the celprm struct
00131 * ----------------------------------------------
00132 * celprt() prints the contents of a celprm struct using wcsprintf().  Mainly
00133 * intended for diagnostic purposes.
00134 *
00135 * Given:
00136 *   cel       const struct celprm*
00137 *                       Celestial transformation parameters.
00138 *
00139 * Function return value:
00140 *             int       Status return value:
00141 *                         0: Success.
00142 *                         1: Null celprm pointer passed.
00143 *
00144 *
00145 * celperr() - Print error messages from a celprm struct
00146 * -----------------------------------------------------
00147 * celperr() prints the error message(s), if any, stored in a celprm struct and
00148 * the prjprm struct that it contains.  If there are no errors then nothing is
00149 * printed.  It uses wcserr_prt(), q.v.
00150 *
00151 * Given:
00152 *   cel       const struct celprm*
00153 *                       Coordinate transformation parameters.
00154 *
00155 *   prefix    const char *
00156 *                       If non-NULL, each output line will be prefixed with
00157 *                       this string.
00158 *
00159 * Function return value:
00160 *             int       Status return value:
00161 *                         0: Success.
00162 *                         1: Null celprm pointer passed.
00163 *
00164 *
00165 * celset() - Setup routine for the celprm struct
00166 * ----------------------------------------------
00167 * celset() sets up a celprm struct according to information supplied within
00168 * it.
00169 *
00170 * Note that this routine need not be called directly; it will be invoked by
00171 * celx2s() and cels2x() if celprm::flag is anything other than a predefined
00172 * magic value.
00173 *
00174 * Given and returned:
00175 *   cel       struct celprm*
00176 *                       Celestial transformation parameters.
00177 *
00178 * Function return value:
00179 *             int       Status return value:
00180 *                         0: Success.
00181 *                         1: Null celprm pointer passed.
00182 *                         2: Invalid projection parameters.
00183 *                         3: Invalid coordinate transformation parameters.
00184 *                         4: Ill-conditioned coordinate transformation
00185 *                            parameters.
00186 *
00187 *                       For returns > 1, a detailed error message is set in
00188 *                       celprm::err if enabled, see wcserr_enable().
00189 *
00190 *
00191 * celx2s() - Pixel-to-world celestial transformation
00192 * --------------------------------------------------
00193 * celx2s() transforms (x,y) coordinates in the plane of projection to
00194 * celestial coordinates (lng,lat).
00195 *
00196 * Given and returned:
```

```
00197 *   cel       struct celprm*
00198 *                       Celestial transformation parameters.
00199 *
00200 * Given:
00201 *   nx,ny     int       Vector lengths.
00202 *
00203 *   sxy,sll   int       Vector strides.
00204 *
00205 *   x,y       const double[]
00206 *                       Projected coordinates in pseudo "degrees".
00207 *
00208 * Returned:
00209 *   phi,theta double[]  Longitude and latitude (phi,theta) in the native
00210 *                       coordinate system of the projection [deg].
00211 *
00212 *   lng,lat   double[]  Celestial longitude and latitude (lng,lat) of the
00213 *                       projected point [deg].
00214 *
00215 *   stat      int[]     Status return value for each vector element:
00216 *                         0: Success.
00217 *                         1: Invalid value of (x,y).
00218 *
00219 * Function return value:
00220 *             int       Status return value:
00221 *                         0: Success.
00222 *                         1: Null celprm pointer passed.
00223 *                         2: Invalid projection parameters.
00224 *                         3: Invalid coordinate transformation parameters.
00225 *                         4: Ill-conditioned coordinate transformation
00226 *                            parameters.
00227 *                         5: One or more of the (x,y) coordinates were
00228 *                            invalid, as indicated by the stat vector.
00229 *
00230 *                       For returns > 1, a detailed error message is set in
00231 *                       celprm::err if enabled, see wcserr_enable().
00232 *
00233 *
00234 * cels2x() - World-to-pixel celestial transformation
00235 * --------------------------------------------------
00236 * cels2x() transforms celestial coordinates (lng,lat) to (x,y) coordinates in
00237 * the plane of projection.
00238 *
00239 * Given and returned:
00240 *   cel       struct celprm*
00241 *                       Celestial transformation parameters.
00242 *
00243 * Given:
00244 *   nlng,nlat int       Vector lengths.
00245 *
00246 *   sll,sxy   int       Vector strides.
00247 *
00248 *   lng,lat   const double[]
00249 *                       Celestial longitude and latitude (lng,lat) of the
00250 *                       projected point [deg].
00251 *
00252 * Returned:
00253 *   phi,theta double[]  Longitude and latitude (phi,theta) in the native
00254 *                       coordinate system of the projection [deg].
00255 *
00256 *   x,y       double[]  Projected coordinates in pseudo "degrees".
00257 *
00258 *   stat      int[]     Status return value for each vector element:
00259 *                         0: Success.
00260 *                         1: Invalid value of (lng,lat).
00261 *
00262 * Function return value:
00263 *             int       Status return value:
00264 *                         0: Success.
00265 *                         1: Null celprm pointer passed.
00266 *                         2: Invalid projection parameters.
00267 *                         3: Invalid coordinate transformation parameters.
00268 *                         4: Ill-conditioned coordinate transformation
00269 *                            parameters.
00270 *                         6: One or more of the (lng,lat) coordinates were
00271 *                            invalid, as indicated by the stat vector.
00272 *
00273 *                       For returns > 1, a detailed error message is set in
00274 *                       celprm::err if enabled, see wcserr_enable().
00275 *
00276 *
00277 * celprm struct - Celestial transformation parameters
00278 * ---------------------------------------------------
00279 * The celprm struct contains information required to transform celestial
00280 * coordinates.  It consists of certain members that must be set by the user
00281 * ("given") and others that are set by the WCSLIB routines ("returned").  Some
00282 * of the latter are supplied for informational purposes and others are for
00283 * internal use only.
```

```
00284 *
00285 * Returned celprm struct members must not be modified by the user.
00286 *
00287 *   int flag
00288 *     (Given and returned) This flag must be set to zero whenever any of the
00289 *     following celprm struct members are set or changed:
00290 *
00291 *       - celprm::offset,
00292 *       - celprm::phi0,
00293 *       - celprm::theta0,
00294 *       - celprm::ref[4],
00295 *       - celprm::prj:
00296 *         - prjprm::code,
00297 *         - prjprm::r0,
00298 *         - prjprm::pv[],
00299 *         - prjprm::phi0,
00300 *         - prjprm::theta0.
00301 *
00302 *     This signals the initialization routine, celset(), to recompute the
00303 *     returned members of the celprm struct.  celset() will reset flag to
00304 *     indicate that this has been done.
00305 *
00306 *   int offset
00307 *     (Given) If true (non-zero), an offset will be applied to (x,y) to
00308 *     force (x,y) = (0,0) at the fiducial point, (phi_0,theta_0).
00309 *     Default is 0 (false).
00310 *
00311 *   double phi0
00312 *     (Given) The native longitude, phi_0 [deg], and ...
00313 *
00314 *   double theta0
00315 *     (Given) ... the native latitude, theta_0 [deg], of the fiducial point,
00316 *     i.e. the point whose celestial coordinates are given in
00317 *     celprm::ref[1:2].  If undefined (set to a magic value by prjini()) the
00318 *     initialization routine, celset(), will set this to a projection-specific
00319 *     default.
00320 *
00321 *   double ref[4]
00322 *     (Given) The first pair of values should be set to the celestial
00323 *     longitude and latitude of the fiducial point [deg] - typically right
00324 *     ascension and declination.  These are given by the CRVALia keywords in
00325 *     FITS.
00326 *
00327 *     (Given and returned) The second pair of values are the native longitude,
00328 *     phi_p [deg], and latitude, theta_p [deg], of the celestial pole (the
00329 *     latter is the same as the celestial latitude of the native pole,
00330 *     delta_p) and these are given by the FITS keywords LONPOLEa and LATPOLEa
00331 *     (or by PVi_2a and PVi_3a attached to the longitude axis which take
00332 *     precedence if defined).
00333 *
00334 *     LONPOLEa defaults to phi_0 (see above) if the celestial latitude of the
00335 *     fiducial point of the projection is greater than or equal to the native
00336 *     latitude, otherwise phi_0 + 180 [deg].  (This is the condition for the
00337 *     celestial latitude to increase in the same direction as the native
00338 *     latitude at the fiducial point.)  ref[2] may be set to UNDEFINED (from
00339 *     wcsmath.h) or 999.0 to indicate that the correct default should be
00340 *     substituted.
00341 *
00342 *     theta_p, the native latitude of the celestial pole (or equally the
00343 *     celestial latitude of the native pole, delta_p) is often determined
00344 *     uniquely by CRVALia and LONPOLEa in which case LATPOLEa is ignored.
00345 *     However, in some circumstances there are two valid solutions for theta_p
00346 *     and LATPOLEa is used to choose between them.  LATPOLEa is set in ref[3]
00347 *     and the solution closest to this value is used to reset ref[3].  It is
00348 *     therefore legitimate, for example, to set ref[3] to +90.0 to choose the
00349 *     more northerly solution - the default if the LATPOLEa keyword is omitted
00350 *     from the FITS header.  For the special case where the fiducial point of
00351 *     the projection is at native latitude zero, its celestial latitude is
00352 *     zero, and LONPOLEa = +/- 90.0 then the celestial latitude of the native
00353 *     pole is not determined by the first three reference values and LATPOLEa
00354 *     specifies it completely.
00355 *
00356 *     The returned value, celprm::latpreq, specifies how LATPOLEa was actually
00357 *     used.
00358 *
00359 *   struct prjprm prj
00360 *     (Given and returned) Projection parameters described in the prologue to
00361 *     prj.h.
00362 *
00363 *   double euler[5]
00364 *     (Returned) Euler angles and associated intermediaries derived from the
00365 *     coordinate reference values.  The first three values are the Z-, X-, and
00366 *     Z'-Euler angles [deg], and the remaining two are the cosine and sine of
00367 *     the X-Euler angle.
00368 *
00369 *   int latpreq
00370 *     (Returned) For informational purposes, this indicates how the LATPOLEa
```

```
00371 *     keyword was used
00372 *       - 0: Not required, theta_p (== delta_p) was determined uniquely by the
00373 *            CRVALia and LONPOLEa keywords.
00374 *       - 1: Required to select between two valid solutions of theta_p.
00375 *       - 2: theta_p was specified solely by LATPOLEa.
00376 *
00377 *   int isolat
00378 *     (Returned) True if the spherical rotation preserves the magnitude of the
00379 *     latitude, which occurs iff the axes of the native and celestial
00380 *     coordinates are coincident.  It signals an opportunity to cache
00381 *     intermediate calculations common to all elements in a vector
00382 *     computation.
00383 *
00384 *   struct wcserr *err
00385 *     (Returned) If enabled, when an error status is returned, this struct
00386 *     contains detailed information about the error, see wcserr_enable().
00387 *
00388 *   void *padding
00389 *     (An unused variable inserted for alignment purposes only.)

Data Structures

- struct dpkey

  *Store for **DP**ja and **DQ**ia keyvalues.*
- struct disprm

  Distortion parameters.

Macros

- #define DISP2X_ARGS
- #define DISX2P_ARGS
- #define DPLEN (sizeof(struct dpkey)/sizeof(int))
- #define DISLEN (sizeof(struct disprm)/sizeof(int))

Enumerations

- enum dis_errmsg_enum {
  DISERR_SUCCESS = 0 , DISERR_NULL_POINTER = 1 , DISERR_MEMORY = 2 , DISERR_BAD_PARAM = 3 ,
  DISERR_DISTORT = 4 , DISERR_DEDISTORT = 5 }

Functions

- int disndp (int n)

  *Memory allocation for **DP**ja and **DQ**ia.*
- int dpfill (struct dpkey *dp, const char *keyword, const char *field, int j, int type, int i, double f)

  Fill the contents of a dpkey struct.
- int dpkeyi (const struct dpkey *dp)

  Get the data value in a dpkey struct as int.
- double dpkeyd (const struct dpkey *dp)

  Get the data value in a dpkey struct as double.
- int disini (int alloc, int naxis, struct disprm *dis)

  Default constructor for the disprm struct.
- int disinit (int alloc, int naxis, struct disprm *dis, int ndpmax)

  Default constructor for the disprm struct.
- int discpy (int alloc, const struct disprm *dissrc, struct disprm *disdst)

  Copy routine for the disprm struct.
- int disfree (struct disprm *dis)

  Destructor for the disprm struct.
- int dissize (const struct disprm *dis, int sizes[2])

  Compute the size of a disprm struct.
- int disprt (const struct disprm *dis)

  Print routine for the disprm struct.
- int disperr (const struct disprm *dis, const char *prefix)

  Print error messages from a disprm struct.
- int dishdo (struct disprm *dis)

  *write FITS headers using **TPD**.*
- int disset (struct disprm *dis)

  Setup routine for the disprm struct.
- int disp2x (struct disprm *dis, const double rawcrd[], double discrd[])

  Apply distortion function.
- int disx2p (struct disprm *dis, const double discrd[], double rawcrd[])

  Apply de-distortion function.
- int diswarp (struct disprm *dis, const double pixblc[], const double pixtrc[], const double pixsamp[], int *nsamp, double maxdis[], double *maxtot, double avgdis[], double *avgtot, double rmsdis[], double *rmstot)

  Compute measures of distortion.

Variables

- const char * dis_errmsg []

  Status return messages.

6.3.1 Detailed Description

Routines in this suite implement extensions to the FITS World Coordinate System (WCS) standard proposed by
"Representations of distortions in FITS world coordinate systems",
Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
available from http://www.atnf.csiro.au/people/Mark.Calabretta

In brief, a distortion function may occupy one of two positions in the WCS algorithm chain. Prior distortions precede the linear transformation matrix, whether it be **PC**i_ja or **CD**i_ja, and sequent distortions follow it. WCS Paper

IV defines FITS keywords used to specify parameters for predefined distortion functions. The following are used for prior distortions:

```
CPDISja   ...(string-valued, identifies the distortion function)
DPja      ...(record-valued, parameters)
CPERRja   ...(floating-valued, maximum value)
```

Their counterparts for sequent distortions are **CQDIS**ia, **DQ**ia, and **CQERR**ia. An additional floating-valued keyword, **DVERR**a, records the maximum value of the combined distortions.

DPja and **DQ**ia are "record-valued". Syntactically, the keyvalues are standard FITS strings, but they are to be interpreted in a special way. The general form is

```
DPja = '<field-specifier>: <float>'
```

where the field-specifier consists of a sequence of fields separated by periods, and the ': ' between the field-specifier and the floating-point value is part of the record syntax. For example:

```
DP1 = 'AXIS.1: 1'
```

Certain field-specifiers are defined for all distortion functions, while others are defined only for particular distortions. Refer to WCS Paper IV for further details. wcspih() parses all distortion keywords and loads them into a disprm struct for analysis by disset() which knows (or possibly does not know) how to interpret them. Of the Paper IV distortion functions, only the general Polynomial distortion is currently implemented here.

TPV - the TPV "projection":

The distortion function component of the **TPV** celestial "projection" is also supported. The **TPV** projection, originally proposed in a draft of WCS Paper II, consists of a **TAN** projection with sequent polynomial distortion, the coefficients of which are encoded in **PV**i_ma keyrecords. Full details may be found at the registry of FITS conventions:

http://fits.gsfc.nasa.gov/registry/tpvwcs/tpv.html

Internally, wcsset() changes **TPV** to a **TAN** projection, translates the **PV**i_ma keywords to **DQ**ia and loads them into a disprm struct. These **DQ**ia keyrecords have the form

```
DQia = 'TPV.m: <value>'
```

where i, a, m, and the value for each **DQ**ia match each **PV**i_ma. Consequently, WCSLIB would handle a FITS header containing these keywords, along with **CQDIS**ia = '**TPV**' and the required **DQ**ia**.NAXES** and **DQ**ia**.AXIS.**ihat keywords.

Note that, as defined, **TPV** assumes that **CD**i_ja is used to define the linear transformation. The section on historical idiosyncrasies (below) cautions about translating **CD**i_ja to **PC**i_ja plus **CDELT**ia in this case.

SIP - Simple Imaging Polynomial:

These routines also support the Simple Imaging Polynomial (**SIP**), whose design was influenced by early drafts of WCS Paper IV. It is described in detail in

http://fits.gsfc.nasa.gov/registry/sip.html

SIP, which is defined only as a prior distortion for 2-D celestial images, has the interesting feature that it records an approximation to the inverse polynomial distortion function. This is used by disx2p() to provide an initial estimate for its more precise iterative inversion. The special-purpose keywords used by **SIP** are parsed and translated by wcspih() as follows:

```
 A_p_q = <value>   ->   DP1 = 'SIP.FWD.p_q: <value>'
AP_p_q = <value>   ->   DP1 = 'SIP.REV.p_q: <value>'
 B_p_q = <value>   ->   DP2 = 'SIP.FWD.p_q: <value>'
BP_p_q = <value>   ->   DP2 = 'SIP.REV.p_q: <value>'
A_DMAX = <value>   ->   DPERR1 = <value>
B_DMAX = <value>   ->   DPERR2 = <value>
```

SIP's **A_ORDER** and **B_ORDER** keywords are not used. WCSLIB would recognise a FITS header containing the above keywords, along with **CPDIS**ja = '**SIP**' and the required **DP**ja**.NAXES** keywords.

DSS - Digitized Sky Survey:

The Digitized Sky Survey resulted from the production of the Guide Star Catalogue for the Hubble Space Telescope. Plate solutions based on a polynomial distortion function were encoded in FITS using non-standard keywords. Sect. 5.2 of WCS Paper IV describes how **DSS** coordinates may be translated to a sequent Polynomial distortion using two auxiliary variables. That translation is based on optimising the non-distortion component of the plate solution.

Following Paper IV, wcspih() translates the non-distortion component of **DSS** coordinates to standard WCS keywords (**CRPIX**ja, **PC**i_ja, **CRVAL**ia, etc), and fills a wcsprm struct with their values. It encodes the **DSS** polynomial coefficients as

```
AMDXm = <value>   ->   DQ1 = 'AMD.m: <value>'
AMDYm = <value>   ->   DQ2 = 'AMD.m: <value>'
```

WCSLIB would recognise a FITS header containing the above keywords, along with **CQDIS**ia = '**DSS**' and the required **DQ**ia**.NAXES** keywords.

WAT - the TNX and ZPX "projections":
The **TNX** and **ZPX** "projections" add a polynomial distortion function to the standard **TAN** and **ZPN** projections respectively. Unusually, the polynomial may be expressed as the sum of Chebyshev or Legendre polynomials, or as a simple sum of monomials, as described in

```
http://fits.gsfc.nasa.gov/registry/tnx/tnx-doc.html
http://fits.gsfc.nasa.gov/registry/zpxwcs/zpx.html
```

The polynomial coefficients are encoded in special-purpose **WAT**i_n keywords as a set of continued strings, thus providing the name for this distortion type. **WAT**i_n are parsed and translated by wcspih() into the following set:

```
DQi = 'WAT.POLY: <value>'
DQi = 'WAT.XMIN: <value>'
DQi = 'WAT.XMAX: <value>'
DQi = 'WAT.YMIN: <value>'
DQi = 'WAT.YMAX: <value>'
DQi = 'WAT.CHBY.m_n: <value>'  or
DQi = 'WAT.LEGR.m_n: <value>'  or
DQi = 'WAT.MONO.m_n: <value>'
```

along with **CQDIS**ia = '**WAT**' and the required **DP**ja**.NAXES** keywords. For **ZPX**, the **ZPN** projection parameters are also encoded in **WAT**i_n, and wcspih() translates these to standard **PV**i_ma.

Note that, as defined, **TNX** and **ZPX** assume that **CD**i_ja is used to define the linear transformation. The section on historical idiosyncrasies (below) cautions about translating **CD**i_ja to **PC**i_ja plus **CDELT**ia in this case.

TPD - Template Polynomial Distortion:
The "Template Polynomial Distortion" (**TPD**) is a superset of the **TPV**, **SIP**, **DSS**, and **WAT** (**TNX** & **ZPX**) polynomial distortions that also supports 1-D usage and inversions. Like **TPV**, **SIP**, and **DSS**, the form of the polynomial is fixed (the "template") and only the coefficients for the required terms are set non-zero. **TPD** generalizes **TPV** in going to 9th degree, **SIP** by accomodating **TPV**'s linear and radial terms, and **DSS** in both respects. While in theory the degree of the **WAT** polynomial distortion in unconstrained, in practice it is limited to values that can be handled by **TPD**.

Within WCSLIB, **TPV**, **SIP**, **DSS**, and **WAT** are all implemented as special cases of **TPD**. Indeed, **TPD** was developed precisely for that purpose. **WAT** distortions expressed as the sum of Chebyshev or Legendre polynomials are expanded for **TPD** as a simple sum of monomials. Moreover, the general Polynomial distortion is translated and implemented internally as **TPD** whenever possible.

However, WCSLIB also recognizes '**TPD**' as a distortion function in its own right (i.e. a recognized value of **CPDIS**ja or **CQDIS**ia), for use as both prior and sequent distortions. Its **DP**ja and **DQ**ia keyrecords have the form

```
DPja = 'TPD.FWD.m: <value>'
DPja = 'TPD.REV.m: <value>'
```

for the forward and reverse distortion functions. Moreover, like the general Polynomial distortion, **TPD** supports auxiliary variables, though only as a linear transformation of pixel coordinates (p1,p2):

```
x = a0 + a1*p1 + a2*p2
y = b0 + b1*p1 + b2*p2
```

where the coefficients of the auxiliary variables (x,y) are recorded as

```
DPja = 'AUX.1.COEFF.0: a0'      ...default 0.0
DPja = 'AUX.1.COEFF.1: a1'      ...default 1.0
DPja = 'AUX.1.COEFF.2: a2'      ...default 0.0
DPja = 'AUX.2.COEFF.0: b0'      ...default 0.0
DPja = 'AUX.2.COEFF.1: b1'      ...default 0.0
DPja = 'AUX.2.COEFF.2: b2'      ...default 1.0
```

Though nowhere near as powerful, in typical applications **TPD** is considerably faster than the general Polynomial distortion. As **TPD** has a finite and not too large number of possible terms (60), the coefficients for each can be

stored (by disset()) in a fixed location in the disprm::dparm[] array. A large part of the speedup then arises from evaluating the polynomial using Horner's scheme.

Separate implementations for polynomials of each degree, and conditionals for 1-D polynomials and 2-D polynomials with and without the radial variable, ensure that unused terms mostly do not impose a significant computational overhead.

The **TPD** terms are as follows

```
0: 1      4: xx       12: xxxx      24: xxxxxx      40: xxxxxxxx
          5: xy       13: xxxy      25: xxxxxy      41: xxxxxxxy
1: x      6: yy       14: xxyy      26: xxxxyy      42: xxxxxxyy
2: y                  15: xyyy      27: xxxyyy      43: xxxxxyyy
3: r      7: xxx      16: yyyy      28: xxyyyy      44: xxxxyyyy
          8: xxy                    29: xyyyyy      45: xxxyyyyy
          9: xyy      17: xxxxx     30: yyyyyy      46: xxyyyyyy
         10: yyy      18: xxxxy                     47: xyyyyyyy
         11: rrr      19: xxxyy     31: xxxxxxx     48: yyyyyyyy
                      20: xxyyy     32: xxxxxxy
                      21: xyyyy     33: xxxxxyy     49: xxxxxxxxx
                      22: yyyyy     34: xxxxyyy     50: xxxxxxxxy
                      23: rrrrr     35: xxxyyyy     51: xxxxxxxyy
                                    36: xxyyyyy     52: xxxxxxyyy
                                    37: xyyyyyy     53: xxxxxyyyy
                                    38: yyyyyyy     54: xxxxyyyyy
                                    39: rrrrrrr     55: xxxyyyyyy
                                                    56: xxyyyyyyy
                                                    57: xyyyyyyyy
                                                    58: yyyyyyyyy
                                                    59: rrrrrrrrr
```

where r = $\sqrt{(x^2 + y^2)}$. Note that even powers of r are excluded since they can be accomodated by powers of $(x^2 + y^2)$.

Note here that "x" refers to the axis to which the distortion function is attached, with "y" being the complementary axis. So, for example, with longitude on axis 1 and latitude on axis 2, for **TPD** attached to axis 1, "x" refers to axis 1 and "y" to axis 2. For **TPD** attached to axis 2, "x" refers to axis 2, and "y" to axis 1.

TPV uses all terms up to 39. The m in its **PV**i_ma keywords translates directly to the **TPD** coefficient number.

SIP uses all terms except for 0, 3, 11, 23, 39, and 59, with terms 1 and 2 only used for the inverse. Its **A**_p_q, etc. keywords must be translated using a map.

DSS uses terms 0, 1, 2, 4, 5, 6, 7, 8, 9, 10, 17, 19, and 21. The presence of a non-zero constant term arises through the use of auxiliary variables with origin offset from the reference point of the **TAN** projection. However, in the translation given by WCS Paper IV, the distortion polynomial is zero, or very close to zero, at the reference pixel itself. The mapping between **DSS**'s **AMDX**m (or **AMDY**m) keyvalues and **TPD** coefficients, while still simple, is not quite as straightforward as for **TPV** and **SIP**.

WAT uses all but the radial terms, namely 3, 11, 23, 39, and 59. While the mapping between **WAT**'s monomial coefficients and **TPD** is fairly simple, for its expression in terms of a sum of Chebyshev or Legendre polynomials it is much less so.

Historical idiosyncrasies:
In addition to the above, some historical distortion functions have further idiosyncrasies that must be taken into account when translating them to **TPD**.

WCS Paper IV specifies that a distortion function returns a correction to be added to pixel coordinates (prior distortion) or intermediate pixel coordinates (sequent distortion). The correction is meant to be small so that ignoring the distortion function, i.e. setting the correction to zero, produces a commensurately small error.

However, rather than an additive correction, some historical distortion functions (**TPV**, **DSS**) define a polynomial that returns the corrected coordinates directly.

The difference between the two approaches is readily accounted for simply by adding or subtracting 1 from the coefficient of the first degree term of the polynomial. However, it opens the way for considerable confusion.

Additional to the formalism of WCS Paper IV, both the Polynomial and **TPD** distortion functions recognise a keyword
```
DPja = 'DOCORR: 0'
```

which is meant to apply generally to indicate that the distortion function returns the corrected coordinates directly. Any other value for **DOCORR** (or its absence) indicates that the distortion function returns an additive correction.

WCS Paper IV also specifies that the independent variables of a distortion function are pixel coordinates (prior distortion) or intermediate pixel coordinates (sequent distortion).

On the contrary, the independent variables of the **SIP** polynomial are pixel coordinate offsets from the reference pixel. This is readily handled via the renormalisation parameters
```
DPja = 'OFFSET.jhat: <value>'
```

where the value corresponds to **CRPIX**ja.

Likewise, because **TPV**, **TNX**, and **ZPX** are defined in terms of **CD**i_ja, the independent variables of the polynomial are intermediate world coordinates rather than intermediate pixel coordinates. Because sequent distortions are always applied before **CDELT**ia, if **CD**i_ja is translated to **PC**i_ja plus **CDELT**ia, then either **CDELT**ia must be unity, or the distortion polynomial coefficients must be adjusted to account for the change of scale.

Summary of the dis routines:
These routines apply the distortion functions defined by the extension to the FITS WCS standard proposed in Paper IV. They are based on the disprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

dpfill(), dpkeyi(), and dpkeyd() are provided to manage the dpkey struct.

disndp(), disini(), disinit(), discpy(), and disfree() are provided to manage the disprm struct, dissize() computes its total size including allocated memory, and disprt() prints its contents.

disperr() prints the error message(s) (if any) stored in a disprm struct.

wcshdo() normally writes **SIP** and **TPV** headers in their native form if at all possible. However, dishdo() may be used to set a flag that tells it to write the header in the form of the **TPD** translation used internally.

A setup routine, disset(), computes intermediate values in the disprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by disset(), though disset() need not be called explicitly - refer to the explanation of disprm::flag.

disp2x() and disx2p() implement the WCS distortion functions, disp2x() using separate functions, such as dispoly() and tpd7(), to do the computation.

An auxiliary routine, diswarp(), computes various measures of the distortion over a specified range of coordinates.

PLEASE NOTE:

6.3.2 Macro Definition Documentation

DISP2X_ARGS

```
#define DISP2X_ARGS
```

Value:
```
int inverse, const int iparm[], const double dparm[], \
int ncrd, const double rawcrd[], double *discrd
```

DISX2P_ARGS

```
#define DISX2P_ARGS
```

Value:

```
int inverse, const int iparm[], const double dparm[], \
int ncrd, const double discrd[], double *rawcrd
```

DPLEN

```
#define DPLEN (sizeof(struct dpkey)/sizeof(int))
```

6.3.4 Function Documentation

disndp()

```
int disndp (
            int n )
```

Memory allocation for **DP**`ja` and **DQ**`ia`.

disndp() sets or gets the value of NDPMAX (default 256). This global variable controls the maximum number of dpkey structs, for holding **DP**`ja` or **DQ**`ia` keyvalues, that disini() should allocate space for. It is also used by disinit() as the default value of ndpmax.

PLEASE NOTE: This function is not thread-safe.

Parameters

in	*n*	Value of NDPMAX; ignored if < 0. Use a value less than zero to get the current value.

Returns

Current value of NDPMAX.

dpfill()

```
int dpfill (
              struct dpkey * dp,
              const char * keyword,
              const char * field,
              int j,
              int type,
              int i,
              double f )
```

Fill the contents of a dpkey struct.

dpfill() is a utility routine to aid in filling the contents of the dpkey struct. No checks are done on the validity of the inputs.

WCS Paper IV specifies the syntax of a record-valued keyword as
`keyword = '<field-specifier>: <float>'`

However, some **DP**ja and **DQ**ia record values, such as those of **DP**ja**.NAXES** and **DP**ja**.AXIS.**j, are intrinsically integer-valued. While FITS header parsers are not expected to know in advance which of **DP**ja and **DQ**ia are integral and which are floating point, if the record's value parses as an integer (i.e. without decimal point or exponent), then preferably enter it into the dpkey struct as an integer. Either way, it doesn't matter as disset() accepts either data type for all record values.

Parameters

in,out	*dp*	Store for **DP**ja and **DQ**ia keyvalues.
in	*keyword*	
in	*field*	These arguments are concatenated with an intervening "." to construct the full record field name, i.e. including the keyword name, **DP**ja or **DQ**ia (but excluding the colon delimiter which is NOT part of the name). Either may be given as a NULL pointer. Set both NULL to omit setting this component of the struct.
in	*j*	Axis number (1-relative), i.e. the j in **DP**ja or i in **DQ**ia. Can be given as 0, in which case the axis number will be obtained from the keyword component of the field name which must either have been given or preset. If j is non-zero, and keyword was given, then the value of j will be used to fill in the axis number.
in	*type*	Data type of the record's value • 0: Integer, • 1: Floating point.
in	*i*	For type == 0, the integer value of the record.
in	*f*	For type == 1, the floating point value of the record.

Returns

Status return value:

- 0: Success.

dpkeyi()

```
int dpkeyi (
              const struct dpkey * dp )
```

Get the data value in a dpkey struct as int.

dpkeyi() returns the data value in a dpkey struct as an integer value.

Parameters

in,out	*dp*	Parsed contents of a **DP**ja or **DQ**ia keyrecord.

Returns

The record's value as int.

dpkeyd()

```
double dpkeyd (
              const struct dpkey * dp )
```

Get the data value in a dpkey struct as double.

dpkeyd() returns the data value in a dpkey struct as a floating point value.

Parameters

in,out	*dp*	Parsed contents of a **DP**ja or **DQ**ia keyrecord.

Returns

The record's value as double.

disini()

```
int disini (
              int alloc,
              int naxis,
              struct disprm * dis )
```

Default constructor for the disprm struct.

disini() is a thin wrapper on **disinit**(). It invokes it with ndpmax set to -1 which causes it to use the value of the global variable NDPMAX. It is thereby potentially thread-unsafe if NDPMAX is altered dynamically via disndp(). Use **disinit**() for a thread-safe alternative in this case.

disinit()

```
int disinit (
             int alloc,
             int naxis,
             struct disprm * dis,
             int ndpmax )
```

Default constructor for the disprm struct.

disinit() allocates memory for arrays in a disprm struct and sets all members of the struct to default values.

PLEASE NOTE: every disprm struct must be initialized by **disinit**(), possibly repeatedly. On the first invokation, and only the first invokation, disprm::flag must be set to -1 to initialize memory management, regardless of whether **disinit**() will actually be used to allocate memory.

Parameters

in	*alloc*	If true, allocate memory unconditionally for arrays in the disprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	*naxis*	The number of world coordinate axes, used to determine array sizes.
in,out	*dis*	Distortion function parameters. Note that, in order to initialize memory management disprm::flag must be set to -1 when dis is initialized for the first time (memory leaks may result if it had already been initialized).
in	*ndpmax*	The number of **DP**ja or **DQ**ia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

discpy()

```
int discpy (
             int alloc,
             const struct disprm * dissrc,
             struct disprm * disdst )
```

Copy routine for the disprm struct.

discpy() does a deep copy of one disprm struct to another, using disinit() to allocate memory unconditionally for its arrays if required. Only the "information to be provided" part of the struct is copied; a call to disset() is required to initialize the remainder.

Parameters

in	*alloc*	If true, allocate memory unconditionally for arrays in the destination. Otherwise, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless.
in	*dissrc*	Struct to copy from.
in,out	*disdst*	Struct to copy to. disprm::flag should be set to -1 if disdst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

disfree()

```
int disfree (
              struct disprm * dis )
```

Destructor for the disprm struct.

disfree() frees memory allocated for the disprm arrays by disinit(). disinit() keeps a record of the memory it allocates and **disfree**() will only attempt to free this.

PLEASE NOTE: disfree() must not be invoked on a disprm struct that was not initialized by disinit().

Parameters

in	*dis*	Distortion function parameters.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

dissize()

```
int dissize (
              const struct disprm * dis,
              int sizes[2] )
```

Compute the size of a disprm struct.

dissize() computes the full size of a disprm struct, including allocated memory.

Parameters

in	*dis*	Distortion function parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct disprm). The second element is the total allocated size, in bytes, assuming that the allocation was done by disini(). This figure includes memory allocated for members of constituent structs, such as disprm::dp. It is not an error for the struct not to have been set up via tabset(), which normally results in additional memory allocation.

Returns

Status return value:

- 0: Success.

disprt()

```
int disprt (
            const struct disprm * dis )
```

Print routine for the disprm struct.

disprt() prints the contents of a disprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*dis*	Distortion function parameters.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

disperr()

```
int disperr (
            const struct disprm * dis,
            const char * prefix )
```

Print error messages from a disprm struct.

disperr() prints the error message(s) (if any) stored in a disprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*dis*	Distortion function parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

dishdo()

```
int dishdo (
            struct disprm * dis )
```

write FITS headers using **TPD**.

dishdo() sets a flag that tells wcshdo() to write FITS headers in the form of the **TPD** translation used internally. Normally **SIP** and **TPV** would be written in their native form if at all possible.

Parameters

in,out	*dis*	Distortion function parameters.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 3: No **TPD** translation.

disset()

```
int disset (
            struct disprm * dis )
```

Setup routine for the disprm struct.

disset(), sets up the disprm struct according to information supplied within it - refer to the explanation of disprm::flag.

Note that this routine need not be called directly; it will be invoked by disp2x() and disx2p() if the disprm::flag is anything other than a predefined magic value.

Parameters

in,out	*dis*	Distortion function parameters.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

- 2: Memory allocation failed.
- 3: Invalid parameter.

For returns > 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

disp2x()

```
int disp2x (
              struct disprm * dis,
              const double rawcrd[],
              double discrd[] )
```

Apply distortion function.

disp2x() applies the distortion functions. By definition, the distortion is in the pixel-to-world direction.

Depending on the point in the algorithm chain at which it is invoked, **disp2x**() may transform pixel coordinates to corrected pixel coordinates, or intermediate pixel coordinates to corrected intermediate pixel coordinates, or image coordinates to corrected image coordinates.

disx2p()

```
int disx2p (
              struct disprm * dis,
              const double discrd[],
              double rawcrd[] )
```

Apply de-distortion function.

disx2p() applies the inverse of the distortion functions. By definition, the de-distortion is in the world-to-pixel direction.

Depending on the point in the algorithm chain at which it is invoked, **disx2p**() may transform corrected pixel coordinates to pixel coordinates, or corrected intermediate pixel coordinates to intermediate pixel coordinates, or corrected image coordinates to image coordinates.

disx2p() iteratively solves for the inverse using disp2x(). It assumes that the distortion is small and the functions are well-behaved, being continuous and with continuous derivatives. Also that, to first order in the neighbourhood of the solution, discrd[j] ∼= a + b∗rawcrd[j], i.e. independent of rawcrd[i], where i != j. This is effectively equivalent to assuming that the distortion functions are separable to first order. Furthermore, a is assumed to be small, and b close to unity.

If disprm::**disx2p**() is defined, then **disx2p**() uses it to provide an initial estimate for its more precise iterative inversion.

Parameters

in,out	*dis*	Distortion function parameters.
in	*discrd*	Array of coordinates.
out	*rawcrd*	Array of coordinates to which the inverse distortion functions have been applied.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid parameter.
- 5: De-distort error.

For returns > 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

diswarp()

```
int diswarp (
              struct disprm * dis,
              const double pixblc[],
              const double pixtrc[],
              const double pixsamp[],
              int * nsamp,
              double maxdis[],
              double * maxtot,
              double avgdis[],
              double * avgtot,
              double rmsdis[],
              double * rmstot )
```

Compute measures of distortion.

diswarp() computes various measures of the distortion over a specified range of coordinates.

For prior distortions, the measures may be interpreted simply as an offset in pixel coordinates. For sequent distortions, the interpretation depends on the nature of the linear transformation matrix (**PC**i_ja or **CD**i_ja). If the latter introduces a scaling, then the measures will also be scaled. Note also that the image domain, which is rectangular in pixel coordinates, may be rotated, skewed, and/or stretched in intermediate pixel coordinates, and in general cannot be defined using pixblc[] and pixtrc[].

PLEASE NOTE: the measures of total distortion may be essentially meaningless if there are multiple sequent distortions with different scaling.

See also linwarp().

Parameters

in,out	*dis*	Distortion function parameters.
in	*pixblc*	Start of the range of pixel coordinates (for prior distortions), or intermediate pixel coordinates (for sequent distortions). May be specified as a NULL pointer which is interpreted as (1,1,...).
in	*pixtrc*	End of the range of pixel coordinates (prior) or intermediate pixel coordinates (sequent).
in	*pixsamp*	If positive or zero, the increment on the particular axis, starting at pixblc[]. Zero is interpreted as a unit increment. pixsamp may also be specified as a NULL pointer which is interpreted as all zeroes, i.e. unit increments on all axes. If negative, the grid size on the particular axis (the absolute value being rounded to the nearest integer). For example, if pixsamp is (-128.0,-128.0,...) then each axis will be sampled at 128 points between pixblc[] and pixtrc[] inclusive. Use caution when using this option on non-square images.

Parameters

out	*nsamp*	The number of pixel coordinates sampled. Can be specified as a NULL pointer if not required.
out	*maxdis*	For each individual distortion function, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	*maxtot*	For the combination of all distortion functions, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	*avgdis*	For each individual distortion function, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	*avgtot*	For the combination of all distortion functions, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	*rmsdis*	For each individual distortion function, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.
out	*rmstot*	For the combination of all distortion functions, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid parameter.
- 4: Distort error.

6.3.5 Variable Documentation

dis_errmsg

```
const char * dis_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

6.4 dis.h

Go to the documentation of this file.

00023 *===========================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the dis routines
00031 * ---------------------------
00032 * Routines in this suite implement extensions to the FITS World Coordinate
00033 * System (WCS) standard proposed by
00034 *
00035 =   "Representations of distortions in FITS world coordinate systems",
00036 =   Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
00037 =   available from http://www.atnf.csiro.au/people/Mark.Calabretta
00038 *
00039 * In brief, a distortion function may occupy one of two positions in the WCS
00040 * algorithm chain.  Prior distortions precede the linear transformation
00041 * matrix, whether it be PCi_ja or CDi_ja, and sequent distortions follow it.
00042 * WCS Paper IV defines FITS keywords used to specify parameters for predefined
00043 * distortion functions.  The following are used for prior distortions:
00044 *
00045 =   CPDISja   ...(string-valued, identifies the distortion function)
00046 =   DPja      ...(record-valued, parameters)
00047 =   CPERRja   ...(floating-valued, maximum value)
00048 *
00049 * Their counterparts for sequent distortions are CQDISia, DQia, and CQERRia.
00050 * An additional floating-valued keyword, DVERRa, records the maximum value of
00051 * the combined distortions.
00052 *
00053 * DPja and DQia are "record-valued".  Syntactically, the keyvalues are
00054 * standard FITS strings, but they are to be interpreted in a special way.
00055 * The general form is
00056 *
00057 =   DPja = '<field-specifier>: <float>'
00058 *
00059 * where the field-specifier consists of a sequence of fields separated by
00060 * periods, and the ': ' between the field-specifier and the floating-point
00061 * value is part of the record syntax.  For example:
00062 *
00063 =   DP1 = 'AXIS.1: 1'
00064 *
00065 * Certain field-specifiers are defined for all distortion functions, while
00066 * others are defined only for particular distortions.  Refer to WCS Paper IV
00067 * for further details.  wcspih() parses all distortion keywords and loads them
00068 * into a disprm struct for analysis by disset() which knows (or possibly does
00069 * not know) how to interpret them.  Of the Paper IV distortion functions, only
00070 * the general Polynomial distortion is currently implemented here.
00071 *
00072 * TPV - the TPV "projection":
00073 * ---------------------------
00074 * The distortion function component of the TPV celestial "projection" is also
00075 * supported.  The TPV projection, originally proposed in a draft of WCS Paper
00076 * II, consists of a TAN projection with sequent polynomial distortion, the
00077 * coefficients of which are encoded in PVi_ma keyrecords.  Full details may be
00078 * found at the registry of FITS conventions:
00079 *
00080 =   http://fits.gsfc.nasa.gov/registry/tpvwcs/tpv.html
00081 *
00082 * Internally, wcsset() changes TPV to a TAN projection, translates the PVi_ma
00083 * keywords to DQia and loads them into a disprm struct.  These DQia keyrecords
00084 * have the form
00085 *
00086 =   DQia = 'TPV.m: <value>'
00087 *
00088 * where i, a, m, and the value for each DQia match each PVi_ma.  Consequently,
00089 * WCSLIB would handle a FITS header containing these keywords, along with
00090 * CQDISia = 'TPV' and the required DQia.NAXES and DQia.AXIS.ihat keywords.
00091 *
00092 * Note that, as defined, TPV assumes that CDi_ja is used to define the linear
00093 * transformation.  The section on historical idiosyncrasies (below) cautions
00094 * about translating CDi_ja to PCi_ja plus CDELTia in this case.
00095 *
00096 * SIP - Simple Imaging Polynomial:
00097 * --------------------------------
00098 * These routines also support the Simple Imaging Polynomial (SIP), whose
00099 * design was influenced by early drafts of WCS Paper IV.  It is described in
```

```
00100 * detail in
00101 *
00102 =   http://fits.gsfc.nasa.gov/registry/sip.html
00103 *
00104 * SIP, which is defined only as a prior distortion for 2-D celestial images,
00105 * has the interesting feature that it records an approximation to the inverse
00106 * polynomial distortion function.  This is used by disx2p() to provide an
00107 * initial estimate for its more precise iterative inversion.  The
00108 * special-purpose keywords used by SIP are parsed and translated by wcspih()
00109 * as follows:
00110 *
00111 =    A_p_q = <value>   ->   DP1 = 'SIP.FWD.p_q: <value>'
00112 =   AP_p_q = <value>   ->   DP1 = 'SIP.REV.p_q: <value>'
00113 =    B_p_q = <value>   ->   DP2 = 'SIP.FWD.p_q: <value>'
00114 =   BP_p_q = <value>   ->   DP2 = 'SIP.REV.p_q: <value>'
00115 =   A_DMAX = <value>   ->   DPERR1 = <value>
00116 =   B_DMAX = <value>   ->   DPERR2 = <value>
00117 *
00118 * SIP's A_ORDER and B_ORDER keywords are not used.  WCSLIB would recognise a
00119 * FITS header containing the above keywords, along with CPDISja = 'SIP' and
00120 * the required DPja.NAXES keywords.
00121 *
00122 * DSS - Digitized Sky Survey:
00123 * ---------------------------
00124 * The Digitized Sky Survey resulted from the production of the Guide Star
00125 * Catalogue for the Hubble Space Telescope.  Plate solutions based on a
00126 * polynomial distortion function were encoded in FITS using non-standard
00127 * keywords.  Sect. 5.2 of WCS Paper IV describes how DSS coordinates may be
00128 * translated to a sequent Polynomial distortion using two auxiliary variables.
00129 * That translation is based on optimising the non-distortion component of the
00130 * plate solution.
00131 *
00132 * Following Paper IV, wcspih() translates the non-distortion component of DSS
00133 * coordinates to standard WCS keywords (CRPIXja, PCi_ja, CRVALia, etc), and
00134 * fills a wcsprm struct with their values.  It encodes the DSS polynomial
00135 * coefficients as
00136 *
00137 =    AMDXm = <value>   ->   DQ1 = 'AMD.m: <value>'
00138 =    AMDYm = <value>   ->   DQ2 = 'AMD.m: <value>'
00139 *
00140 * WCSLIB would recognise a FITS header containing the above keywords, along
00141 * with CQDISia = 'DSS' and the required DQia.NAXES keywords.
00142 *
00143 * WAT - the TNX and ZPX "projections":
00144 * ------------------------------------
00145 * The TNX and ZPX "projections" add a polynomial distortion function to the
00146 * standard TAN and ZPN projections respectively.  Unusually, the polynomial
00147 * may be expressed as the sum of Chebyshev or Legendre polynomials, or as a
00148 * simple sum of monomials, as described in
00149 *
00150 =   http://fits.gsfc.nasa.gov/registry/tnx/tnx-doc.html
00151 =   http://fits.gsfc.nasa.gov/registry/zpxwcs/zpx.html
00152 *
00153 * The polynomial coefficients are encoded in special-purpose WATi_n keywords
00154 * as a set of continued strings, thus providing the name for this distortion
00155 * type.  WATi_n are parsed and translated by wcspih() into the following set:
00156 *
00157 =    DQi = 'WAT.POLY: <value>'
00158 =    DQi = 'WAT.XMIN: <value>'
00159 =    DQi = 'WAT.XMAX: <value>'
00160 =    DQi = 'WAT.YMIN: <value>'
00161 =    DQi = 'WAT.YMAX: <value>'
00162 =    DQi = 'WAT.CHBY.m_n: <value>'  or
00163 =    DQi = 'WAT.LEGR.m_n: <value>'  or
00164 =    DQi = 'WAT.MONO.m_n: <value>'
00165 *
00166 * along with CQDISia = 'WAT' and the required DPja.NAXES keywords.  For ZPX,
00167 * the ZPN projection parameters are also encoded in WATi_n, and wcspih()
00168 * translates these to standard PVi_ma.
00169 *
00170 * Note that, as defined, TNX and ZPX assume that CDi_ja is used to define the
00171 * linear transformation.  The section on historical idiosyncrasies (below)
00172 * cautions about translating CDi_ja to PCi_ja plus CDELTia in this case.
00173 *
00174 * TPD - Template Polynomial Distortion:
00175 * -------------------------------------
00176 * The "Template Polynomial Distortion" (TPD) is a superset of the TPV, SIP,
00177 * DSS, and WAT (TNX & ZPX) polynomial distortions that also supports 1-D usage
00178 * and inversions.  Like TPV, SIP, and DSS, the form of the polynomial is fixed
00179 * (the "template") and only the coefficients for the required terms are set
00180 * non-zero.  TPD generalizes TPV in going to 9th degree, SIP by accomodating
00181 * TPV's linear and radial terms, and DSS in both respects.  While in theory
00182 * the degree of the WAT polynomial distortion in unconstrained, in practice it
00183 * is limited to values that can be handled by TPD.
00184 *
00185 * Within WCSLIB, TPV, SIP, DSS, and WAT are all implemented as special cases
00186 * of TPD.  Indeed, TPD was developed precisely for that purpose.  WAT
```

```
00187 * distortions expressed as the sum of Chebyshev or Legendre polynomials are
00188 * expanded for TPD as a simple sum of monomials.  Moreover, the general
00189 * Polynomial distortion is translated and implemented internally as TPD
00190 * whenever possible.
00191 *
00192 * However, WCSLIB also recognizes 'TPD' as a distortion function in its own
00193 * right (i.e. a recognized value of CPDISja or CQDISia), for use as both prior
00194 * and sequent distortions.  Its DPja and DQia keyrecords have the form
00195 *
00196 =   DPja = 'TPD.FWD.m: <value>'
00197 =   DPja = 'TPD.REV.m: <value>'
00198 *
00199 * for the forward and reverse distortion functions.  Moreover, like the
00200 * general Polynomial distortion, TPD supports auxiliary variables, though only
00201 * as a linear transformation of pixel coordinates (p1,p2):
00202 *
00203 =   x = a0 + a1*p1 + a2*p2
00204 =   y = b0 + b1*p1 + b2*p2
00205 *
00206 * where the coefficients of the auxiliary variables (x,y) are recorded as
00207 *
00208 =   DPja = 'AUX.1.COEFF.0: a0'      ...default 0.0
00209 =   DPja = 'AUX.1.COEFF.1: a1'      ...default 1.0
00210 =   DPja = 'AUX.1.COEFF.2: a2'      ...default 0.0
00211 =   DPja = 'AUX.2.COEFF.0: b0'      ...default 0.0
00212 =   DPja = 'AUX.2.COEFF.1: b1'      ...default 0.0
00213 =   DPja = 'AUX.2.COEFF.2: b2'      ...default 1.0
00214 *
00215 * Though nowhere near as powerful, in typical applications TPD is considerably
00216 * faster than the general Polynomial distortion.  As TPD has a finite and not
00217 * too large number of possible terms (60), the coefficients for each can be
00218 * stored (by disset()) in a fixed location in the disprm::dparm[] array.  A
00219 * large part of the speedup then arises from evaluating the polynomial using
00220 * Horner's scheme.
00221 *
00222 * Separate implementations for polynomials of each degree, and conditionals
00223 * for 1-D polynomials and 2-D polynomials with and without the radial
00224 * variable, ensure that unused terms mostly do not impose a significant
00225 * computational overhead.
00226 *
00227 * The TPD terms are as follows
00228 *
00229 =   0: 1     4: xx      12: xxxx      24: xxxxxx      40: xxxxxxxx
00230 =            5: xy      13: xxxy      25: xxxxxy      41: xxxxxxxy
00231 =   1: x     6: yy      14: xxyy      26: xxxxyy      42: xxxxxxyy
00232 =   2: y                15: xyyy      27: xxxyyy      43: xxxxxyyy
00233 =   3: r     7: xxx     16: yyyy      28: xxyyyy      44: xxxxyyyy
00234 =            8: xxy                   29: xyyyyy      45: xxxyyyyy
00235 =            9: xyy     17: xxxxx     30: yyyyyy      46: xxyyyyyy
00236 =           10: yyy     18: xxxxy                     47: xyyyyyyy
00237 =           11: rrr     19: xxxyy     31: xxxxxxx     48: yyyyyyyy
00238 =                       20: xxyyy     32: xxxxxxy
00239 =                       21: xyyyy     33: xxxxxyy     49: xxxxxxxxx
00240 =                       22: yyyyy     34: xxxxyyy     50: xxxxxxxxy
00241 =                       23: rrrrr     35: xxxyyyy     51: xxxxxxxyy
00242 =                                     36: xxyyyyy     52: xxxxxxyyy
00243 =                                     37: xyyyyyy     53: xxxxxyyyy
00244 =                                     38: yyyyyyy     54: xxxxyyyyy
00245 =                                     39: rrrrrrr     55: xxxyyyyyy
00246 =                                                     56: xxyyyyyyy
00247 =                                                     57: xyyyyyyyy
00248 =                                                     58: yyyyyyyyy
00249 =                                                     59: rrrrrrrrr
00250 *
00251 * where r = sqrt(xx + yy).  Note that even powers of r are excluded since they
00252 * can be accomodated by powers of (xx + yy).
00253 *
00254 * Note here that "x" refers to the axis to which the distortion function is
00255 * attached, with "y" being the complementary axis.  So, for example, with
00256 * longitude on axis 1 and latitude on axis 2, for TPD attached to axis 1, "x"
00257 * refers to axis 1 and "y" to axis 2.  For TPD attached to axis 2, "x" refers
00258 * to axis 2, and "y" to axis 1.
00259 *
00260 * TPV uses all terms up to 39.  The m in its PVi_ma keywords translates
00261 * directly to the TPD coefficient number.
00262 *
00263 * SIP uses all terms except for 0, 3, 11, 23, 39, and 59, with terms 1 and 2
00264 * only used for the inverse.  Its A_p_q, etc. keywords must be translated
00265 * using a map.
00266 *
00267 * DSS uses terms 0, 1, 2, 4, 5, 6, 7, 8, 9, 10, 17, 19, and 21.  The presence
00268 * of a non-zero constant term arises through the use of auxiliary variables
00269 * with origin offset from the reference point of the TAN projection.  However,
00270 * in the translation given by WCS Paper IV, the distortion polynomial is zero,
00271 * or very close to zero, at the reference pixel itself.  The mapping between
00272 * DSS's AMDXm (or AMDYm) keyvalues and TPD coefficients, while still simple,
00273 * is not quite as straightforward as for TPV and SIP.
```

```
00274 *
00275 * WAT uses all but the radial terms, namely 3, 11, 23, 39, and 59.  While the
00276 * mapping between WAT's monomial coefficients and TPD is fairly simple, for
00277 * its expression in terms of a sum of Chebyshev or Legendre polynomials it is
00278 * much less so.
00279 *
00280 * Historical idiosyncrasies:
00281 * --------------------------
00282 * In addition to the above, some historical distortion functions have further
00283 * idiosyncrasies that must be taken into account when translating them to TPD.
00284 *
00285 * WCS Paper IV specifies that a distortion function returns a correction to be
00286 * added to pixel coordinates (prior distortion) or intermediate pixel
00287 * coordinates (sequent distortion).  The correction is meant to be small so
00288 * that ignoring the distortion function, i.e. setting the correction to zero,
00289 * produces a commensurately small error.
00290 *
00291 * However, rather than an additive correction, some historical distortion
00292 * functions (TPV, DSS) define a polynomial that returns the corrected
00293 * coordinates directly.
00294 *
00295 * The difference between the two approaches is readily accounted for simply by
00296 * adding or subtracting 1 from the coefficient of the first degree term of the
00297 * polynomial.  However, it opens the way for considerable confusion.
00298 *
00299 * Additional to the formalism of WCS Paper IV, both the Polynomial and TPD
00300 * distortion functions recognise a keyword
00301 *
00302 =   DPja = 'DOCORR: 0'
00303 *
00304 * which is meant to apply generally to indicate that the distortion function
00305 * returns the corrected coordinates directly.  Any other value for DOCORR (or
00306 * its absence) indicates that the distortion function returns an additive
00307 * correction.
00308 *
00309 * WCS Paper IV also specifies that the independent variables of a distortion
00310 * function are pixel coordinates (prior distortion) or intermediate pixel
00311 * coordinates (sequent distortion).
00312 *
00313 * On the contrary, the independent variables of the SIP polynomial are pixel
00314 * coordinate offsets from the reference pixel.  This is readily handled via
00315 * the renormalisation parameters
00316 *
00317 =   DPja = 'OFFSET.jhat: <value>'
00318 *
00319 * where the value corresponds to CRPIXja.
00320 *
00321 * Likewise, because TPV, TNX, and ZPX are defined in terms of CDi_ja, the
00322 * independent variables of the polynomial are intermediate world coordinates
00323 * rather than intermediate pixel coordinates.  Because sequent distortions
00324 * are always applied before CDELTia, if CDi_ja is translated to PCi_ja plus
00325 * CDELTia, then either CDELTia must be unity, or the distortion polynomial
00326 * coefficients must be adjusted to account for the change of scale.
00327 *
00328 * Summary of the dis routines:
00329 * ----------------------------
00330 * These routines apply the distortion functions defined by the extension to
00331 * the FITS WCS standard proposed in Paper IV.  They are based on the disprm
00332 * struct which contains all information needed for the computations.  The
00333 * struct contains some members that must be set by the user, and others that
00334 * are maintained by these routines, somewhat like a C++ class but with no
00335 * encapsulation.
00336 *
00337 * dpfill(), dpkeyi(), and dpkeyd() are provided to manage the dpkey struct.
00338 *
00339 * disndp(), disini(), disinit(), discpy(), and disfree() are provided to
00340 * manage the disprm struct, dissize() computes its total size including
00341 * allocated memory, and disprt() prints its contents.
00342 *
00343 * disperr() prints the error message(s) (if any) stored in a disprm struct.
00344 *
00345 * wcshdo() normally writes SIP and TPV headers in their native form if at all
00346 * possible.  However, dishdo() may be used to set a flag that tells it to
00347 * write the header in the form of the TPD translation used internally.
00348 *
00349 * A setup routine, disset(), computes intermediate values in the disprm struct
00350 * from parameters in it that were supplied by the user.  The struct always
00351 * needs to be set up by disset(), though disset() need not be called
00352 * explicitly - refer to the explanation of disprm::flag.
00353 *
00354 * disp2x() and disx2p() implement the WCS distortion functions, disp2x() using
00355 * separate functions, such as dispoly() and tpd7(), to do the computation.
00356 *
00357 * An auxiliary routine, diswarp(), computes various measures of the distortion
00358 * over a specified range of coordinates.
00359 *
00360 * PLEASE NOTE: Distortions are not yet handled by wcsbth(), or wcscompare().
```

```
00361 *
00362 *
00363 * disndp() - Memory allocation for DPja and DQia
00364 * ---------------------------------------------
00365 * disndp() sets or gets the value of NDPMAX (default 256).  This global
00366 * variable controls the maximum number of dpkey structs, for holding DPja or
00367 * DQia keyvalues, that disini() should allocate space for.  It is also used by
00368 * disinit() as the default value of ndpmax.
00369 *
00370 * PLEASE NOTE: This function is not thread-safe.
00371 *
00372 * Given:
00373 *   n          int       Value of NDPMAX; ignored if < 0.  Use a value less
00374 *                        than zero to get the current value.
00375 *
00376 * Function return value:
00377 *              int       Current value of NDPMAX.
00378 *
00379 *
00380 * dpfill() - Fill the contents of a dpkey struct
00381 * ----------------------------------------------
00382 * dpfill() is a utility routine to aid in filling the contents of the dpkey
00383 * struct.  No checks are done on the validity of the inputs.
00384 *
00385 * WCS Paper IV specifies the syntax of a record-valued keyword as
00386 *
00387 =   keyword = '<field-specifier>: <float>'
00388 *
00389 * However, some DPja and DQia record values, such as those of DPja.NAXES and
00390 * DPja.AXIS.j, are intrinsically integer-valued.  While FITS header parsers
00391 * are not expected to know in advance which of DPja and DQia are integral and
00392 * which are floating point, if the record's value parses as an integer (i.e.
00393 * without decimal point or exponent), then preferably enter it into the dpkey
00394 * struct as an integer.  Either way, it doesn't matter as disset() accepts
00395 * either data type for all record values.
00396 *
00397 * Given and returned:
00398 *   dp         struct dpkey*
00399 *                        Store for DPja and DQia keyvalues.
00400 *
00401 * Given:
00402 *   keyword    const char *
00403 *   field      const char *
00404 *                        These arguments are concatenated with an intervening
00405 *                        "." to construct the full record field name, i.e.
00406 *                        including the keyword name, DPja or DQia (but
00407 *                        excluding the colon delimiter which is NOT part of the
00408 *                        name).  Either may be given as a NULL pointer.  Set
00409 *                        both NULL to omit setting this component of the
00410 *                        struct.
00411 *
00412 *   j          int       Axis number (1-relative), i.e. the j in DPja or
00413 *                        i in DQia.  Can be given as 0, in which case the axis
00414 *                        number will be obtained from the keyword component of
00415 *                        the field name which must either have been given or
00416 *                        preset.
00417 *
00418 *                        If j is non-zero, and keyword was given, then the
00419 *                        value of j will be used to fill in the axis number.
00420 *
00421 *   type       int       Data type of the record's value
00422 *                          0: Integer,
00423 *                          1: Floating point.
00424 *
00425 *   i          int       For type == 0, the integer value of the record.
00426 *
00427 *   f          double    For type == 1, the floating point value of the record.
00428 *
00429 * Function return value:
00430 *              int       Status return value:
00431 *                          0: Success.
00432 *
00433 *
00434 * dpkeyi() - Get the data value in a dpkey struct as int
00435 * ------------------------------------------------------
00436 * dpkeyi() returns the data value in a dpkey struct as an integer value.
00437 *
00438 * Given and returned:
00439 *   dp         const struct dpkey *
00440 *                        Parsed contents of a DPja or DQia keyrecord.
00441 *
00442 * Function return value:
00443 *              int       The record's value as int.
00444 *
00445 *
00446 * dpkeyd() - Get the data value in a dpkey struct as double
00447 * ---------------------------------------------------------
```

```
00448 * dpkeyd() returns the data value in a dpkey struct as a floating point
00449 * value.
00450 *
00451 * Given and returned:
00452 *   dp        const struct dpkey *
00453 *                       Parsed contents of a DPja or DQia keyrecord.
00454 *
00455 * Function return value:
00456 *             double    The record's value as double.
00457 *
00458 *
00459 * disini() - Default constructor for the disprm struct
00460 * ----------------------------------------------------
00461 * disini() is a thin wrapper on disinit().  It invokes it with ndpmax set
00462 * to -1 which causes it to use the value of the global variable NDPMAX.  It
00463 * is thereby potentially thread-unsafe if NDPMAX is altered dynamically via
00464 * disndp().  Use disinit() for a thread-safe alternative in this case.
00465 *
00466 *
00467 * disinit() - Default constructor for the disprm struct
00468 * ----------------------------------------------------
00469 * disinit() allocates memory for arrays in a disprm struct and sets all
00470 * members of the struct to default values.
00471 *
00472 * PLEASE NOTE: every disprm struct must be initialized by disinit(), possibly
00473 * repeatedly.  On the first invokation, and only the first invokation,
00474 * disprm::flag must be set to -1 to initialize memory management, regardless
00475 * of whether disinit() will actually be used to allocate memory.
00476 *
00477 * Given:
00478 *   alloc     int       If true, allocate memory unconditionally for arrays in
00479 *                       the disprm struct.
00480 *
00481 *                       If false, it is assumed that pointers to these arrays
00482 *                       have been set by the user except if they are null
00483 *                       pointers in which case memory will be allocated for
00484 *                       them regardless.  (In other words, setting alloc true
00485 *                       saves having to initalize these pointers to zero.)
00486 *
00487 *   naxis     int       The number of world coordinate axes, used to determine
00488 *                       array sizes.
00489 *
00490 * Given and returned:
00491 *   dis       struct disprm*
00492 *                       Distortion function parameters.  Note that, in order
00493 *                       to initialize memory management disprm::flag must be
00494 *                       set to -1 when dis is initialized for the first time
00495 *                       (memory leaks may result if it had already been
00496 *                       initialized).
00497 *
00498 * Given:
00499 *   ndpmax    int       The number of DPja or DQia keywords to allocate space
00500 *                       for.  If set to -1, the value of the global variable
00501 *                       NDPMAX will be used.  This is potentially
00502 *                       thread-unsafe if disndp() is being used dynamically to
00503 *                       alter its value.
00504 *
00505 * Function return value:
00506 *             int       Status return value:
00507 *                         0: Success.
00508 *                         1: Null disprm pointer passed.
00509 *                         2: Memory allocation failed.
00510 *
00511 *                       For returns > 1, a detailed error message is set in
00512 *                       disprm::err if enabled, see wcserr_enable().
00513 *
00514 *
00515 * discpy() - Copy routine for the disprm struct
00516 * ---------------------------------------------
00517 * discpy() does a deep copy of one disprm struct to another, using disinit()
00518 * to allocate memory unconditionally for its arrays if required.  Only the
00519 * "information to be provided" part of the struct is copied; a call to
00520 * disset() is required to initialize the remainder.
00521 *
00522 * Given:
00523 *   alloc     int       If true, allocate memory unconditionally for arrays in
00524 *                       the destination.  Otherwise, it is assumed that
00525 *                       pointers to these arrays have been set by the user
00526 *                       except if they are null pointers in which case memory
00527 *                       will be allocated for them regardless.
00528 *
00529 *   dissrc    const struct disprm*
00530 *                       Struct to copy from.
00531 *
00532 * Given and returned:
00533 *   disdst    struct disprm*
00534 *                       Struct to copy to.  disprm::flag should be set to -1
```

```
00535 *                       if disdst was not previously initialized (memory leaks
00536 *                       may result if it was previously initialized).
00537 *
00538 * Function return value:
00539 *             int       Status return value:
00540 *                         0: Success.
00541 *                         1: Null disprm pointer passed.
00542 *                         2: Memory allocation failed.
00543 *
00544 *                       For returns > 1, a detailed error message is set in
00545 *                       disprm::err if enabled, see wcserr_enable().
00546 *
00547 *
00548 * disfree() - Destructor for the disprm struct
00549 * --------------------------------------------
00550 * disfree() frees memory allocated for the disprm arrays by disinit().
00551 * disinit() keeps a record of the memory it allocates and disfree() will only
00552 * attempt to free this.
00553 *
00554 * PLEASE NOTE: disfree() must not be invoked on a disprm struct that was not
00555 * initialized by disinit().
00556 *
00557 * Given:
00558 *   dis       struct disprm*
00559 *                       Distortion function parameters.
00560 *
00561 * Function return value:
00562 *             int       Status return value:
00563 *                         0: Success.
00564 *                         1: Null disprm pointer passed.
00565 *
00566 *
00567 * dissize() - Compute the size of a disprm struct
00568 * ----------------------------------------------
00569 * dissize() computes the full size of a disprm struct, including allocated
00570 * memory.
00571 *
00572 * Given:
00573 *   dis       const struct disprm*
00574 *                       Distortion function parameters.
00575 *
00576 *                       If NULL, the base size of the struct and the allocated
00577 *                       size are both set to zero.
00578 *
00579 * Returned:
00580 *   sizes     int[2]    The first element is the base size of the struct as
00581 *                       returned by sizeof(struct disprm).  The second element
00582 *                       is the total allocated size, in bytes, assuming that
00583 *                       the allocation was done by disini().  This figure
00584 *                       includes memory allocated for members of constituent
00585 *                       structs, such as disprm::dp.
00586 *
00587 *                       It is not an error for the struct not to have been set
00588 *                       up via tabset(), which normally results in additional
00589 *                       memory allocation.
00590 *
00591 * Function return value:
00592 *             int       Status return value:
00593 *                         0: Success.
00594 *
00595 *
00596 * disprt() - Print routine for the disprm struct
00597 * ----------------------------------------------
00598 * disprt() prints the contents of a disprm struct using wcsprintf().  Mainly
00599 * intended for diagnostic purposes.
00600 *
00601 * Given:
00602 *   dis       const struct disprm*
00603 *                       Distortion function parameters.
00604 *
00605 * Function return value:
00606 *             int       Status return value:
00607 *                         0: Success.
00608 *                         1: Null disprm pointer passed.
00609 *
00610 *
00611 * disperr() - Print error messages from a disprm struct
00612 * -----------------------------------------------------
00613 * disperr() prints the error message(s) (if any) stored in a disprm struct.
00614 * If there are no errors then nothing is printed.  It uses wcserr_prt(), q.v.
00615 *
00616 * Given:
00617 *   dis       const struct disprm*
00618 *                       Distortion function parameters.
00619 *
00620 *   prefix    const char *
00621 *                       If non-NULL, each output line will be prefixed with
```

```
00622 *                       this string.
00623 *
00624 * Function return value:
00625 *             int       Status return value:
00626 *                         0: Success.
00627 *                         1: Null disprm pointer passed.
00628 *
00629 *
00630 * dishdo() - write FITS headers using TPD
00631 * ---------------------------------------
00632 * dishdo() sets a flag that tells wcshdo() to write FITS headers in the form
00633 * of the TPD translation used internally.  Normally SIP and TPV would be
00634 * written in their native form if at all possible.
00635 *
00636 * Given and returned:
00637 *   dis       struct disprm*
00638 *                       Distortion function parameters.
00639 *
00640 * Function return value:
00641 *             int       Status return value:
00642 *                         0: Success.
00643 *                         1: Null disprm pointer passed.
00644 *                         3: No TPD translation.
00645 *
00646 *
00647 * disset() - Setup routine for the disprm struct
00648 * ----------------------------------------------
00649 * disset(), sets up the disprm struct according to information supplied within
00650 * it - refer to the explanation of disprm::flag.
00651 *
00652 * Note that this routine need not be called directly; it will be invoked by
00653 * disp2x() and disx2p() if the disprm::flag is anything other than a
00654 * predefined magic value.
00655 *
00656 * Given and returned:
00657 *   dis       struct disprm*
00658 *                       Distortion function parameters.
00659 *
00660 * Function return value:
00661 *             int       Status return value:
00662 *                         0: Success.
00663 *                         1: Null disprm pointer passed.
00664 *                         2: Memory allocation failed.
00665 *                         3: Invalid parameter.
00666 *
00667 *                       For returns > 1, a detailed error message is set in
00668 *                       disprm::err if enabled, see wcserr_enable().
00669 *
00670 *
00671 * disp2x() - Apply distortion function
00672 * ------------------------------------
00673 * disp2x() applies the distortion functions.  By definition, the distortion
00674 * is in the pixel-to-world direction.
00675 *
00676 * Depending on the point in the algorithm chain at which it is invoked,
00677 * disp2x() may transform pixel coordinates to corrected pixel coordinates, or
00678 * intermediate pixel coordinates to corrected intermediate pixel coordinates,
00679 * or image coordinates to corrected image coordinates.
00680 *
00681 *
00682 * Given and returned:
00683 *   dis       struct disprm*
00684 *                       Distortion function parameters.
00685 *
00686 * Given:
00687 *   rawcrd    const double[naxis]
00688 *                       Array of coordinates.
00689 *
00690 * Returned:
00691 *   discrd    double[naxis]
00692 *                       Array of coordinates to which the distortion functions
00693 *                       have been applied.
00694 *
00695 * Function return value:
00696 *             int       Status return value:
00697 *                         0: Success.
00698 *                         1: Null disprm pointer passed.
00699 *                         2: Memory allocation failed.
00700 *                         3: Invalid parameter.
00701 *                         4: Distort error.
00702 *
00703 *                       For returns > 1, a detailed error message is set in
00704 *                       disprm::err if enabled, see wcserr_enable().
00705 *
00706 *
00707 * disx2p() - Apply de-distortion function
00708 * ---------------------------------------
```

```
00709 * disx2p() applies the inverse of the distortion functions.  By definition,
00710 * the de-distortion is in the world-to-pixel direction.
00711 *
00712 * Depending on the point in the algorithm chain at which it is invoked,
00713 * disx2p() may transform corrected pixel coordinates to pixel coordinates, or
00714 * corrected intermediate pixel coordinates to intermediate pixel coordinates,
00715 * or corrected image coordinates to image coordinates.
00716 *
00717 * disx2p() iteratively solves for the inverse using disp2x().  It assumes
00718 * that the distortion is small and the functions are well-behaved, being
00719 * continuous and with continuous derivatives.  Also that, to first order
00720 * in the neighbourhood of the solution, discrd[j] ~= a + b*rawcrd[j], i.e.
00721 * independent of rawcrd[i], where i != j.  This is effectively equivalent to
00722 * assuming that the distortion functions are separable to first order.
00723 * Furthermore, a is assumed to be small, and b close to unity.
00724 *
00725 * If disprm::disx2p() is defined, then disx2p() uses it to provide an initial
00726 * estimate for its more precise iterative inversion.
00727 *
00728 * Given and returned:
00729 *   dis       struct disprm*
00730 *                       Distortion function parameters.
00731 *
00732 * Given:
00733 *   discrd    const double[naxis]
00734 *                       Array of coordinates.
00735 *
00736 * Returned:
00737 *   rawcrd    double[naxis]
00738 *                       Array of coordinates to which the inverse distortion
00739 *                       functions have been applied.
00740 *
00741 * Function return value:
00742 *             int       Status return value:
00743 *                         0: Success.
00744 *                         1: Null disprm pointer passed.
00745 *                         2: Memory allocation failed.
00746 *                         3: Invalid parameter.
00747 *                         5: De-distort error.
00748 *
00749 *                       For returns > 1, a detailed error message is set in
00750 *                       disprm::err if enabled, see wcserr_enable().
00751 *
00752 *
00753 * diswarp() - Compute measures of distortion
00754 * ------------------------------------------
00755 * diswarp() computes various measures of the distortion over a specified range
00756 * of coordinates.
00757 *
00758 * For prior distortions, the measures may be interpreted simply as an offset
00759 * in pixel coordinates.  For sequent distortions, the interpretation depends
00760 * on the nature of the linear transformation matrix (PCi_ja or CDi_ja).  If
00761 * the latter introduces a scaling, then the measures will also be scaled.
00762 * Note also that the image domain, which is rectangular in pixel coordinates,
00763 * may be rotated, skewed, and/or stretched in intermediate pixel coordinates,
00764 * and in general cannot be defined using pixblc[] and pixtrc[].
00765 *
00766 * PLEASE NOTE: the measures of total distortion may be essentially meaningless
00767 * if there are multiple sequent distortions with different scaling.
00768 *
00769 * See also linwarp().
00770 *
00771 * Given and returned:
00772 *   dis       struct disprm*
00773 *                       Distortion function parameters.
00774 *
00775 * Given:
00776 *   pixblc    const double[naxis]
00777 *                       Start of the range of pixel coordinates (for prior
00778 *                       distortions), or intermediate pixel coordinates (for
00779 *                       sequent distortions).  May be specified as a NULL
00780 *                       pointer which is interpreted as (1,1,...).
00781 *
00782 *   pixtrc    const double[naxis]
00783 *                       End of the range of pixel coordinates (prior) or
00784 *                       intermediate pixel coordinates (sequent).
00785 *
00786 *   pixsamp   const double[naxis]
00787 *                       If positive or zero, the increment on the particular
00788 *                       axis, starting at pixblc[].  Zero is interpreted as a
00789 *                       unit increment.  pixsamp may also be specified as a
00790 *                       NULL pointer which is interpreted as all zeroes, i.e.
00791 *                       unit increments on all axes.
00792 *
00793 *                       If negative, the grid size on the particular axis (the
00794 *                       absolute value being rounded to the nearest integer).
00795 *                       For example, if pixsamp is (-128.0,-128.0,...) then
```

```
00796 *                      each axis will be sampled at 128 points between
00797 *                      pixblc[] and pixtrc[] inclusive.  Use caution when
00798 *                      using this option on non-square images.
00799 *
00800 * Returned:
00801 *   nsamp     int*      The number of pixel coordinates sampled.
00802 *
00803 *                      Can be specified as a NULL pointer if not required.
00804 *
00805 *   maxdis    double[naxis]
00806 *                      For each individual distortion function, the
00807 *                      maximum absolute value of the distortion.
00808 *
00809 *                      Can be specified as a NULL pointer if not required.
00810 *
00811 *   maxtot    double*   For the combination of all distortion functions, the
00812 *                      maximum absolute value of the distortion.
00813 *
00814 *                      Can be specified as a NULL pointer if not required.
00815 *
00816 *   avgdis    double[naxis]
00817 *                      For each individual distortion function, the
00818 *                      mean value of the distortion.
00819 *
00820 *                      Can be specified as a NULL pointer if not required.
00821 *
00822 *   avgtot    double*   For the combination of all distortion functions, the
00823 *                      mean value of the distortion.
00824 *
00825 *                      Can be specified as a NULL pointer if not required.
00826 *
00827 *   rmsdis    double[naxis]
00828 *                      For each individual distortion function, the
00829 *                      root mean square deviation of the distortion.
00830 *
00831 *                      Can be specified as a NULL pointer if not required.
00832 *
00833 *   rmstot    double*   For the combination of all distortion functions, the
00834 *                      root mean square deviation of the distortion.
00835 *
00836 *                      Can be specified as a NULL pointer if not required.
00837 *
00838 * Function return value:
00839 *             int       Status return value:
00840 *                         0: Success.
00841 *                         1: Null disprm pointer passed.
00842 *                         2: Memory allocation failed.
00843 *                         3: Invalid parameter.
00844 *                         4: Distort error.
00845 *
00846 *
00847 * disprm struct - Distortion parameters
00848 * ------------------------------------
00849 * The disprm struct contains all of the information required to apply a set of
00850 * distortion functions.  It consists of certain members that must be set by
00851 * the user ("given") and others that are set by the WCSLIB routines
00852 * ("returned").  While the addresses of the arrays themselves may be set by
00853 * disinit() if it (optionally) allocates memory, their contents must be set by
00854 * the user.
00855 *
00856 *   int flag
00857 *     (Given and returned) This flag must be set to zero whenever any of the
00858 *     following members of the disprm struct are set or modified:
00859 *
00860 *       - disprm::naxis,
00861 *       - disprm::dtype,
00862 *       - disprm::ndp,
00863 *       - disprm::dp.
00864 *
00865 *     This signals the initialization routine, disset(), to recompute the
00866 *     returned members of the disprm struct.  disset() will reset flag to
00867 *     indicate that this has been done.
00868 *
00869 *     PLEASE NOTE: flag must be set to -1 when disinit() is called for the
00870 *     first time for a particular disprm struct in order to initialize memory
00871 *     management.  It must ONLY be used on the first initialization otherwise
00872 *     memory leaks may result.
00873 *
00874 *   int naxis
00875 *     (Given or returned) Number of pixel and world coordinate elements.
00876 *
00877 *     If disinit() is used to initialize the disprm struct (as would normally
00878 *     be the case) then it will set naxis from the value passed to it as a
00879 *     function argument.  The user should not subsequently modify it.
00880 *
00881 *   char (*dtype)[72]
00882 *     (Given) Pointer to the first element of an array of char[72] containing
```

```
00883 *     the name of the distortion function for each axis.
00884 *
00885 *   int ndp
00886 *     (Given) The number of entries in the disprm::dp[] array.
00887 *
00888 *   int ndpmax
00889 *     (Given) The length of the disprm::dp[] array.
00890 *
00891 *     ndpmax will be set by disinit() if it allocates memory for disprm::dp[],
00892 *     otherwise it must be set by the user.  See also disndp().
00893 *
00894 *   struct dpkey dp
00895 *     (Given) Address of the first element of an array of length ndpmax of
00896 *     dpkey structs.
00897 *
00898 *     As a FITS header parser encounters each DPja or DQia keyword it should
00899 *     load it into a dpkey struct in the array and increment ndp.  However,
00900 *     note that a single disprm struct must hold only DPja or DQia keyvalues,
00901 *     not both.  disset() interprets them as required by the particular
00902 *     distortion function.
00903 *
00904 *   double *maxdis
00905 *     (Given) Pointer to the first element of an array of double specifying
00906 *     the maximum absolute value of the distortion for each axis computed over
00907 *     the whole image.
00908 *
00909 *     It is not necessary to reset the disprm struct (via disset()) when
00910 *     disprm::maxdis is changed.
00911 *
00912 *   double totdis
00913 *     (Given) The maximum absolute value of the combination of all distortion
00914 *     functions specified as an offset in pixel coordinates computed over the
00915 *     whole image.
00916 *
00917 *     It is not necessary to reset the disprm struct (via disset()) when
00918 *     disprm::totdis is changed.
00919 *
00920 *   int *docorr
00921 *     (Returned) Pointer to the first element of an array of int containing
00922 *     flags that indicate the mode of correction for each axis.
00923 *
00924 *     If docorr is zero, the distortion function returns the corrected
00925 *     coordinates directly.  Any other value indicates that the distortion
00926 *     function computes a correction to be added to pixel coordinates (prior
00927 *     distortion) or intermediate pixel coordinates (sequent distortion).
00928 *
00929 *   int *Nhat
00930 *     (Returned) Pointer to the first element of an array of int containing
00931 *     the number of coordinate axes that form the independent variables of the
00932 *     distortion function for each axis.
00933 *
00934 *   int **axmap
00935 *     (Returned) Pointer to the first element of an array of int* containing
00936 *     pointers to the first elements of the axis mapping arrays for each axis.
00937 *
00938 *     An axis mapping associates the independent variables of a distortion
00939 *     function with the 0-relative image axis number.  For example, consider
00940 *     an image with a spectrum on the first axis (axis 0), followed by RA
00941 *     (axis 1), Dec (axis2), and time (axis 3) axes.  For a distortion in
00942 *     (RA,Dec) and no distortion on the spectral or time axes, the axis
00943 *     mapping arrays, axmap[j][], would be
00944 *
00945 =       j=0: [-1, -1, -1, -1]   ...no  distortion on spectral axis,
00946 =         1: [ 1,  2, -1, -1]   ...RA  distortion depends on RA and Dec,
00947 =         2: [ 2,  1, -1, -1]   ...Dec distortion depends on Dec and RA,
00948 =         3: [-1, -1, -1, -1]   ...no  distortion on time axis,
00949 *
00950 *     where -1 indicates that there is no corresponding independent
00951 *     variable.
00952 *
00953 *   double **offset
00954 *     (Returned) Pointer to the first element of an array of double*
00955 *     containing pointers to the first elements of arrays of offsets used to
00956 *     renormalize the independent variables of the distortion function for
00957 *     each axis.
00958 *
00959 *     The offsets are subtracted from the independent variables before
00960 *     scaling.
00961 *
00962 *   double **scale
00963 *     (Returned) Pointer to the first element of an array of double*
00964 *     containing pointers to the first elements of arrays of scales used to
00965 *     renormalize the independent variables of the distortion function for
00966 *     each axis.
00967 *
00968 *     The scale is applied to the independent variables after the offsets are
00969 *     subtracted.
```

```
00970 *
00971 *   int **iparm
00972 *     (Returned) Pointer to the first element of an array of int*
00973 *     containing pointers to the first elements of the arrays of integer
00974 *     distortion parameters for each axis.
00975 *
00976 *   double **dparm
00977 *     (Returned) Pointer to the first element of an array of double*
00978 *     containing pointers to the first elements of the arrays of floating
00979 *     point distortion parameters for each axis.
00980 *
00981 *   int i_naxis
00982 *     (Returned) Dimension of the internal arrays (normally equal to naxis).
00983 *
00984 *   int ndis
00985 *     (Returned) The number of distortion functions.
00986 *
00987 *   struct wcserr *err
00988 *     (Returned) If enabled, when an error status is returned, this struct
00989 *     contains detailed information about the error, see wcserr_enable().
00990 *
00991 *   int (**disp2x)(DISP2X_ARGS)
00992 *     (For internal use only.)
00993 *   int (**disx2p)(DISX2P_ARGS)
00994 *     (For internal use only.)
00995 *   double *dummy
00996 *     (For internal use only.)
00997 *   int m_flag
00998 *     (For internal use only.)
00999 *   int m_naxis
01000 *     (For internal use only.)
01001 *   char (*m_dtype)[72]
01002 *     (For internal use only.)
01003 *   double **m_dp
01004 *     (For internal use only.)
01005 *   double *m_maxdis
01006 *     (For internal use only.)
01007 *
01008 *
01009 * dpkey struct - Store for DPja and DQia keyvalues
01010 * ------------------------------------------------
01011 * The dpkey struct is used to pass the parsed contents of DPja or DQia
01012 * keyrecords to disset() via the disprm struct.  A disprm struct must hold
01013 * only DPja or DQia keyvalues, not both.
01014 *
01015 * All members of this struct are to be set by the user.
01016 *
01017 *   char field[72]
01018 *     (Given) The full field name of the record, including the keyword name.
01019 *     Note that the colon delimiter separating the field name and the value in
01020 *     record-valued keyvalues is not part of the field name.  For example, in
01021 *     the following:
01022 *
01023 =       DP3A = 'AXIS.1: 2'
01024 *
01025 *     the full record field name is "DP3A.AXIS.1", and the record's value
01026 *     is 2.
01027 *
01028 *   int j
01029 *     (Given) Axis number (1-relative), i.e. the j in DPja or i in DQia.
01030 *
01031 *   int type
01032 *     (Given) The data type of the record's value
01033 *       - 0: Integer (stored as an int),
01034 *       - 1: Floating point (stored as a double).
01035 *
01036 *   union value
01037 *     (Given) A union comprised of
01038 *       - dpkey::i,
01039 *       - dpkey::f,
01040 *
01041 *     the record's value.
01042 *
01043 *
01044 * Global variable: const char *dis_errmsg[] - Status return messages
01045 * ------------------------------------------------------------------
01046 * Error messages to match the status value returned from each function.
01047 *
01048 *===========================================================================*/

Functions

- int fitshdr (const char header[ ], int nkeyrec, int nkeyids, struct fitskeyid keyids[ ], int *nreject, struct fitskey **keys)

  FITS header parser routine.

Variables

- const char * fitshdr_errmsg [ ]

  Status return messages.

6.5.1 Detailed Description

The Flexible Image Transport System (FITS), is a data format widely used in astronomy for data interchange and archive. It is described in

```
"Definition of the Flexible Image Transport System (FITS), version 3.0",
Pence, W.D., Chiappetti, L., Page, C.G., Shaw, R.A., & Stobie, E. 2010,
A&A, 524, A42 - http://dx.doi.org/10.1051/0004-6361/201015362
```

See also http:
fitshdr() is a generic FITS header parser provided to handle keyrecords that are ignored by the WCS header parsers, wcspih() and wcsbth(). Typically the latter may be set to remove WCS keyrecords from a header leaving fitshdr() to handle the remainder.

6.5.2 Macro Definition Documentation

FITSHDR_KEYWORD

```
#define FITSHDR_KEYWORD 0x01
```

Flag bit indicating illegal keyword syntax.

Bit mask for the status flag bit-vector returned by fitshdr() indicating illegal keyword syntax.

FITSHDR_KEYVALUE

```
#define FITSHDR_KEYVALUE 0x02
```

Flag bit indicating illegal keyvalue syntax.

Bit mask for the status flag bit-vector returned by fitshdr() indicating illegal keyvalue syntax.

FITSHDR_COMMENT

```
#define FITSHDR_COMMENT 0x04
```

Flag bit indicating illegal keycomment syntax.

Bit mask for the status flag bit-vector returned by fitshdr() indicating illegal keycomment syntax.

FITSHDR_KEYREC

```
#define FITSHDR_KEYREC 0x08
```

Flag bit indicating illegal keyrecord.

Bit mask for the status flag bit-vector returned by fitshdr() indicating an illegal keyrecord, e.g. an END keyrecord with trailing text.

FITSHDR_CARD

```
#define FITSHDR_CARD 0x08
```

Deprecated.

Deprecated Added for backwards compatibility, use *FITSHDR_KEYREC* instead.

FITSHDR_TRAILER

```
#define FITSHDR_TRAILER 0x10
```

Flag bit indicating keyrecord following a valid END keyrecord.

Bit mask for the status flag bit-vector returned by fitshdr() indicating a keyrecord following a valid END keyrecord.

KEYIDLEN

```
#define KEYIDLEN (sizeof(struct fitskeyid)/sizeof(int))
```

KEYLEN

```
#define KEYLEN (sizeof(struct fitskey)/sizeof(int))
```

6.5.3 Typedef Documentation

int64

```
int64
```

64-bit signed integer data type.

64-bit signed integer data type defined via preprocessor macro WCSLIB_INT64 which may be defined in wcsconfig.h. For example
```
#define WCSLIB_INT64 long long int
```

This is typedef'd in fitshdr.h as
```
#ifdef WCSLIB_INT64
  typedef WCSLIB_INT64 int64;
#else
  typedef int int64[3];
#endif
```

See fitskey::type.

6.5.4 Enumeration Type Documentation

fitshdr_errmsg_enum

```
enum fitshdr_errmsg_enum
```

Enumerator

FITSHDRERR_SUCCESS	
FITSHDRERR_NULL_POINTER	
FITSHDRERR_MEMORY	
FITSHDRERR_FLEX_PARSER	
FITSHDRERR_DATA_TYPE	

6.5.5 Function Documentation

fitshdr()

```
int fitshdr (
            const char header[],
            int nkeyrec,
            int nkeyids,
            struct fitskeyid keyids[],
            int * nreject,
            struct fitskey ** keys )
```

FITS header parser routine.

fitshdr() parses a character array containing a FITS header, extracting all keywords and their values into an array of fitskey structs.

Parameters

in	*header*	Character array containing the (entire) FITS header, for example, as might be obtained conveniently via the CFITSIO routine fits_hdr2str(). Each header "keyrecord" (formerly "card image") consists of exactly 80 7-bit ASCII printing characters in the range 0x20 to 0x7e (which excludes NUL, BS, TAB, LF, FF and CR) especially noting that the keyrecords are NOT null-terminated.
in	*nkeyrec*	Number of keyrecords in header[].
in	*nkeyids*	Number of entries in keyids[].
in,out	*keyids*	While all keywords are extracted from the header, keyids[] provides a convienient way of indexing them. The fitskeyid struct contains three members; fitskeyid::name must be set by the user while fitskeyid::count and fitskeyid::idx are returned by **fitshdr**(). All matched keywords will have their fitskey::keyno member negated.
out	*nreject*	Number of header keyrecords rejected for syntax errors.
out	*keys*	Pointer to an array of nkeyrec fitskey structs containing all keywords and keyvalues extracted from the header. Memory for the array is allocated by **fitshdr**() and this must be freed by the user. See wcsdealloc().

Returns

Status return value:

- 0: Success.
- 1: Null fitskey pointer passed.
- 2: Memory allocation failed.
- 3: Fatal error returned by Flex parser.
- 4: Unrecognised data type.

Notes:

1. Keyword parsing is done in accordance with the syntax defined by NOST 100-2.0, noting the following points in particular:

   a Sect. 5.1.2.1 specifies that keywords be left-justified in columns 1-8, blank-filled with no embedded spaces, composed only of the ASCII characters **ABCDEFGHJKLMNOPQRSTUVWXYZ0123456789-**↩
   _
   fitshdr() accepts any characters in columns 1-8 but flags keywords that do not conform to standard syntax.

   b Sect. 5.1.2.2 defines the "value indicator" as the characters "**= **" occurring in columns 9 and 10. If these are absent then the keyword has no value and columns 9-80 may contain any ASCII text (but see note 2 for **CONTINUE** keyrecords). This is copied to the comment member of the fitskey struct.

   c Sect. 5.1.2.3 states that a keyword may have a null (undefined) value if the value/comment field, columns 11-80, consists entirely of spaces, possibly followed by a comment.

   d Sect. 5.1.1 states that trailing blanks in a string keyvalue are not significant and the parser always removes them. A string containing nothing but blanks will be replaced with a single blank.

   Sect. 5.2.1 also states that a quote character (**'**) in a string value is to be represented by two successive quote characters and the parser removes the repeated quote.

e The parser recognizes free-format character (NOST 100-2.0, Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values (Sect. 5.2.4) for all keywords.

f Sect. 5.2.3 offers no comment on the size of an integer keyvalue except indirectly in limiting it to 70 digits. The parser will translate an integer keyvalue to a 32-bit signed integer if it lies in the range -2147483648 to +2147483647, otherwise it interprets it as a 64-bit signed integer if possible, or else a "very long" integer (see fitskey::type).

g **END** not followed by 77 blanks is not considered to be a legitimate end keyrecord.

2. The parser supports a generalization of the OGIP Long String Keyvalue Convention (v1.0) whereby strings may be continued onto successive header keyrecords. A keyrecord contains a segment of a continued string if and only if

   a it contains the pseudo-keyword **CONTINUE**,

   b columns 9 and 10 are both blank,

   c columns 11 to 80 contain what would be considered a valid string keyvalue, including optional keycomment, if column 9 had contained '**=**',

   d the previous keyrecord contained either a valid string keyvalue or a valid **CONTINUE** keyrecord.

   If any of these conditions is violated, the keyrecord is considered in isolation.

   Syntax errors in keycomments in a continued string are treated more permissively than usual; the '**/**' delimiter may be omitted provided that parsing of the string keyvalue is not compromised. However, the FITSHDR_↩ COMMENT status bit will be set for the keyrecord (see fitskey::status).

   As for normal strings, trailing blanks in a continued string are not significant.

   In the OGIP convention "the '**&**' character is used as the last non-blank character of the string to indicate that the string is (probably) continued on the following keyword". This additional syntax is not required by **fitshdr**(), but if '**&**' does occur as the last non-blank character of a continued string keyvalue then it will be removed, along with any trailing blanks. However, blanks that occur before the '**&**' will be preserved.

6.5.6 Variable Documentation

fitshdr_errmsg

```
const char * fitshdr_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

00044 * to handle the remainder.
00045 *
00046 *
00047 * fitshdr() - FITS header parser routine
00048 * --------------------------------------
00049 * fitshdr() parses a character array containing a FITS header, extracting
00050 * all keywords and their values into an array of fitskey structs.
00051 *
00052 * Given:
00053 *   header    const char []
00054 *                       Character array containing the (entire) FITS header,
00055 *                       for example, as might be obtained conveniently via the
00056 *                       CFITSIO routine fits_hdr2str().
00057 *
00058 *                       Each header "keyrecord" (formerly "card image")
00059 *                       consists of exactly 80 7-bit ASCII printing characters
00060 *                       in the range 0x20 to 0x7e (which excludes NUL, BS,
00061 *                       TAB, LF, FF and CR) especially noting that the
00062 *                       keyrecords are NOT null-terminated.
00063 *
00064 *   nkeyrec   int       Number of keyrecords in header[].
00065 *
00066 *   nkeyids   int       Number of entries in keyids[].
00067 *
00068 * Given and returned:
00069 *   keyids    struct fitskeyid []
00070 *                       While all keywords are extracted from the header,
00071 *                       keyids[] provides a convienient way of indexing them.
00072 *                       The fitskeyid struct contains three members;
00073 *                       fitskeyid::name must be set by the user while
00074 *                       fitskeyid::count and fitskeyid::idx are returned by
00075 *                       fitshdr().  All matched keywords will have their
00076 *                       fitskey::keyno member negated.
00077 *
00078 * Returned:
00079 *   nreject   int*      Number of header keyrecords rejected for syntax
00080 *                       errors.
00081 *
00082 *   keys      struct fitskey**
00083 *                       Pointer to an array of nkeyrec fitskey structs
00084 *                       containing all keywords and keyvalues extracted from
00085 *                       the header.
00086 *
00087 *                       Memory for the array is allocated by fitshdr() and
00088 *                       this must be freed by the user.  See wcsdealloc().
00089 *
00090 * Function return value:
00091 *             int       Status return value:
00092 *                         0: Success.
00093 *                         1: Null fitskey pointer passed.
00094 *                         2: Memory allocation failed.
00095 *                         3: Fatal error returned by Flex parser.
00096 *                         4: Unrecognised data type.
00097 *
00098 * Notes:
00099 *   1: Keyword parsing is done in accordance with the syntax defined by
00100 *      NOST 100-2.0, noting the following points in particular:
00101 *
00102 *      a: Sect. 5.1.2.1 specifies that keywords be left-justified in columns
00103 *         1-8, blank-filled with no embedded spaces, composed only of the
00104 *         ASCII characters ABCDEFGHJKLMNOPQRSTUVWXYZ0123456789-_
```

```
00105 *
00106 *         fitshdr() accepts any characters in columns 1-8 but flags keywords
00107 *         that do not conform to standard syntax.
00108 *
00109 *      b: Sect. 5.1.2.2 defines the "value indicator" as the characters "= "
00110 *         occurring in columns 9 and 10.  If these are absent then the
00111 *         keyword has no value and columns 9-80 may contain any ASCII text
00112 *         (but see note 2 for CONTINUE keyrecords).  This is copied to the
00113 *         comment member of the fitskey struct.
00114 *
00115 *      c: Sect. 5.1.2.3 states that a keyword may have a null (undefined)
00116 *         value if the value/comment field, columns 11-80, consists entirely
00117 *         of spaces, possibly followed by a comment.
00118 *
00119 *      d: Sect. 5.1.1 states that trailing blanks in a string keyvalue are
00120 *         not significant and the parser always removes them.  A string
00121 *         containing nothing but blanks will be replaced with a single
00122 *         blank.
00123 *
00124 *         Sect. 5.2.1 also states that a quote character (') in a string
00125 *         value is to be represented by two successive quote characters and
00126 *         the parser removes the repeated quote.
00127 *
00128 *      e: The parser recognizes free-format character (NOST 100-2.0,
00129 *         Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values
00130 *         (Sect. 5.2.4) for all keywords.
00131 *
00132 *      f: Sect. 5.2.3 offers no comment on the size of an integer keyvalue
00133 *         except indirectly in limiting it to 70 digits.  The parser will
00134 *         translate an integer keyvalue to a 32-bit signed integer if it
00135 *         lies in the range -2147483648 to +2147483647, otherwise it
00136 *         interprets it as a 64-bit signed integer if possible, or else a
00137 *         "very long" integer (see fitskey::type).
00138 *
00139 *      g: END not followed by 77 blanks is not considered to be a legitimate
00140 *         end keyrecord.
00141 *
00142 *   2: The parser supports a generalization of the OGIP Long String Keyvalue
00143 *      Convention (v1.0) whereby strings may be continued onto successive
00144 *      header keyrecords.  A keyrecord contains a segment of a continued
00145 *      string if and only if
00146 *
00147 *      a: it contains the pseudo-keyword CONTINUE,
00148 *
00149 *      b: columns 9 and 10 are both blank,
00150 *
00151 *      c: columns 11 to 80 contain what would be considered a valid string
00152 *         keyvalue, including optional keycomment, if column 9 had contained
00153 *         '=',
00154 *
00155 *      d: the previous keyrecord contained either a valid string keyvalue or
00156 *         a valid CONTINUE keyrecord.
00157 *
00158 *      If any of these conditions is violated, the keyrecord is considered in
00159 *      isolation.
00160 *
00161 *      Syntax errors in keycomments in a continued string are treated more
00162 *      permissively than usual; the '/' delimiter may be omitted provided that
00163 *      parsing of the string keyvalue is not compromised.  However, the
00164 *      FITSHDR_COMMENT status bit will be set for the keyrecord (see
00165 *      fitskey::status).
00166 *
00167 *      As for normal strings, trailing blanks in a continued string are not
00168 *      significant.
00169 *
00170 *      In the OGIP convention "the '&' character is used as the last non-blank
00171 *      character of the string to indicate that the string is (probably)
00172 *      continued on the following keyword".  This additional syntax is not
00173 *      required by fitshdr(), but if '&' does occur as the last non-blank
00174 *      character of a continued string keyvalue then it will be removed, along
00175 *      with any trailing blanks.  However, blanks that occur before the '&'
00176 *      will be preserved.
00177 *
00178 *
00179 * fitskeyid struct - Keyword indexing
00180 * -----------------------------------
00181 * fitshdr() uses the fitskeyid struct to return indexing information for
00182 * specified keywords.  The struct contains three members, the first of which,
00183 * fitskeyid::name, must be set by the user with the remainder returned by
00184 * fitshdr().
00185 *
00186 *   char name[12]:
00187 *     (Given) Name of the required keyword.  This is to be set by the user;
00188 *     the '.' character may be used for wildcarding.  Trailing blanks will be
00189 *     replaced with nulls.
00190 *
00191 *   int count:
```

```
00192 *     (Returned) The number of matches found for the keyword.
00193 *
00194 *   int idx[2]:
00195 *     (Returned) Indices into keys[], the array of fitskey structs returned by
00196 *     fitshdr().  Note that these are 0-relative array indices, not keyrecord
00197 *     numbers.
00198 *
00199 *     If the keyword is found in the header the first index will be set to the
00200 *     array index of its first occurrence, otherwise it will be set to -1.
00201 *
00202 *     If multiples of the keyword are found, the second index will be set to
00203 *     the array index of its last occurrence, otherwise it will be set to -1.
00204 *
00205 *
00206 * fitskey struct - Keyword/value information
00207 * -----------------------------------------
00208 * fitshdr() returns an array of fitskey structs, each of which contains the
00209 * result of parsing one FITS header keyrecord.  All members of the fitskey
00210 * struct are returned by fitshdr(), none are given by the user.
00211 *
00212 *   int keyno
00213 *     (Returned) Keyrecord number (1-relative) in the array passed as input to
00214 *     fitshdr().  This will be negated if the keyword matched any specified in
00215 *     the keyids[] index.
00216 *
00217 *   int keyid
00218 *     (Returned) Index into the first entry in keyids[] with which the
00219 *     keyrecord matches, else -1.
00220 *
00221 *   int status
00222 *     (Returned) Status flag bit-vector for the header keyrecord employing the
00223 *     following bit masks defined as preprocessor macros:
00224 *
00225 *       - FITSHDR_KEYWORD:    Illegal keyword syntax.
00226 *       - FITSHDR_KEYVALUE:   Illegal keyvalue syntax.
00227 *       - FITSHDR_COMMENT:    Illegal keycomment syntax.
00228 *       - FITSHDR_KEYREC:     Illegal keyrecord, e.g. an END keyrecord with
00229 *                             trailing text.
00230 *       - FITSHDR_TRAILER:    Keyrecord following a valid END keyrecord.
00231 *
00232 *     The header keyrecord is syntactically correct if no bits are set.
00233 *
00234 *   char keyword[12]
00235 *     (Returned) Keyword name, null-filled for keywords of less than eight
00236 *     characters (trailing blanks replaced by nulls).
00237 *
00238 *     Use
00239 *
00240 =       sprintf(dst, "%.8s", keyword)
00241 *
00242 *     to copy it to a character array with null-termination, or
00243 *
00244 =       sprintf(dst, "%8.8s", keyword)
00245 *
00246 *     to blank-fill to eight characters followed by null-termination.
00247 *
00248 *   int type
00249 *     (Returned) Keyvalue data type:
00250 *       - 0: No keyvalue (both the value and type are undefined).
00251 *       - 1: Logical, represented as int.
00252 *       - 2: 32-bit signed integer.
00253 *       - 3: 64-bit signed integer (see below).
00254 *       - 4: Very long integer (see below).
00255 *       - 5: Floating point (stored as double).
00256 *       - 6: Integer complex (stored as double[2]).
00257 *       - 7: Floating point complex (stored as double[2]).
00258 *       - 8: String.
00259 *       - 8+10*n: Continued string (described below and in fitshdr() note 2).
00260 *
00261 *     A negative type indicates that a syntax error was encountered when
00262 *     attempting to parse a keyvalue of the particular type.
00263 *
00264 *     Comments on particular data types:
00265 *       - 64-bit signed integers lie in the range
00266 *
00267 =           (-9223372036854775808 <= int64 <  -2147483648) ||
00268 =                    (+2147483647 <  int64 <= +9223372036854775807)
00269 *
00270 *         A native 64-bit data type may be defined via preprocessor macro
00271 *         WCSLIB_INT64 defined in wcsconfig.h, e.g. as 'long long int'; this
00272 *         will be typedef'd to 'int64' here.  If WCSLIB_INT64 is not set, then
00273 *         int64 is typedef'd to int[3] instead and fitskey::keyvalue is to be
00274 *         computed as
00275 *
00276 =           ((keyvalue.k[2]) * 1000000000 +
00277 =             keyvalue.k[1]) * 1000000000 +
00278 =             keyvalue.k[0]
```

```
00279 *
00280 *         and may reported via
00281 *
00282 =            if (keyvalue.k[2]) {
00283 =              printf("%d%09d%09d", keyvalue.k[2], abs(keyvalue.k[1]),
00284 =                                   abs(keyvalue.k[0]));
00285 =            } else {
00286 =              printf("%d%09d", keyvalue.k[1], abs(keyvalue.k[0]));
00287 =            }
00288 *
00289 *         where keyvalue.k[0] and keyvalue.k[1] range from -999999999 to
00290 *         +999999999.
00291 *
00292 *       - Very long integers, up to 70 decimal digits in length, are encoded
00293 *         in keyvalue.l as an array of int[8], each of which stores 9 decimal
00294 *         digits.  fitskey::keyvalue is to be computed as
00295 *
00296 =           (((((((keyvalue.l[7]) * 1000000000 +
00297 =                 keyvalue.l[6]) * 1000000000 +
00298 =                 keyvalue.l[5]) * 1000000000 +
00299 =                 keyvalue.l[4]) * 1000000000 +
00300 =                 keyvalue.l[3]) * 1000000000 +
00301 =                 keyvalue.l[2]) * 1000000000 +
00302 =                 keyvalue.l[1]) * 1000000000 +
00303 =                 keyvalue.l[0]
00304 *
00305 *       - Continued strings are not reconstructed, they remain split over
00306 *         successive fitskey structs in the keys[] array returned by
00307 *         fitshdr().  fitskey::keyvalue data type, 8 + 10n, indicates the
00308 *         segment number, n, in the continuation.
00309 *
00310 *   int padding
00311 *     (An unused variable inserted for alignment purposes only.)
00312 *
00313 *   union keyvalue
00314 *     (Returned) A union comprised of
00315 *
00316 *       - fitskey::i,
00317 *       - fitskey::k,
00318 *       - fitskey::l,
00319 *       - fitskey::f,
00320 *       - fitskey::c,
00321 *       - fitskey::s,
00322 *
00323 *     used by the fitskey struct to contain the value associated with a
00324 *     keyword.
00325 *
00326 *   int i
00327 *     (Returned) Logical (fitskey::type == 1) and 32-bit signed integer
00328 *     (fitskey::type == 2) data types in the fitskey::keyvalue union.
00329 *
00330 *   int64 k
00331 *     (Returned) 64-bit signed integer (fitskey::type == 3) data type in the
00332 *     fitskey::keyvalue union.
00333 *
00334 *   int l[8]
00335 *     (Returned) Very long integer (fitskey::type == 4) data type in the
00336 *     fitskey::keyvalue union.
00337 *
00338 *   double f
00339 *     (Returned) Floating point (fitskey::type == 5) data type in the
00340 *     fitskey::keyvalue union.
00341 *
00342 *   double c[2]
00343 *     (Returned) Integer and floating point complex (fitskey::type == 6 || 7)
00344 *     data types in the fitskey::keyvalue union.
00345 *
00346 *   char s[72]
00347 *     (Returned) Null-terminated string (fitskey::type == 8) data type in the
00348 *     fitskey::keyvalue union.
00349 *
00350 *   int ulen
00351 *     (Returned) Where a keycomment contains a units string in the standard
00352 *     form, e.g. [m/s], the ulen member indicates its length, inclusive of
00353 *     square brackets.  Otherwise ulen is zero.
00354 *
00355 *   char comment[84]
00356 *     (Returned) Keycomment, i.e. comment associated with the keyword or, for
00357 *     keyrecords rejected because of syntax errors, the compete keyrecord
00358 *     itself with null-termination.
00359 *
00360 *     Comments are null-terminated with trailing spaces removed.  Leading
00361 *     spaces are also removed from keycomments (i.e. those immediately
00362 *     following the '/' character), but not from COMMENT or HISTORY keyrecords
00363 *     or keyrecords without a value indicator ("= " in columns 9-80).
00364 *
00365 *
```

Data Structures

- struct wtbarr

  Extraction of coordinate lookup tables from BINTABLE.

Functions

- int fits_read_wcstab (fitsfile *fptr, int nwtb, wtbarr *wtb, int *status)

  *FITS '**TAB**' table reading routine.*

6.7.1 Detailed Description

fits_read_wcstab(), an implementation of a FITS table reading routine for '**TAB**' coordinates, is provided for CFITSIO programmers. It has been incorporated into CFITSIO as of v3.006 with the definitions in this file, getwcstab.h, moved into fitsio.h.

fits_read_wcstab() is not included in the WCSLIB object library but the source code is presented here as it may be useful for programmers using an older version of CFITSIO than 3.006, or as a programming template for non-CFITSIO programmers.

6.7.2 Function Documentation

fits_read_wcstab()

```
int fits_read_wcstab (
            fitsfile * fptr,
            int nwtb,
            wtbarr * wtb,
            int * status )
```

FITS '**TAB**' table reading routine.

fits_read_wcstab() extracts arrays from a binary table required in constructing '**TAB**' coordinates.

Parameters

in	*fptr*	Pointer to the file handle returned, for example, by the fits_open_file() routine in CFITSIO.
in	*nwtb*	Number of arrays to be read from the binary table(s).
in,out	*wtb*	Address of the first element of an array of wtbarr typedefs. This wtbarr typedef is defined to match the wtbarr struct defined in WCSLIB. An array of such structs returned by the WCSLIB function wcstab() as discussed in the notes below.
out	*status*	CFITSIO status value.

Returns

CFITSIO status value.

Notes:

1. In order to maintain WCSLIB and CFITSIO as independent libraries it is not permissible for any CFITSIO library code to include WCSLIB header files, or vice versa. However, the CFITSIO function **fits_read_wcstab**() accepts an array of wtbarr structs defined in wcs.h within WCSLIB.

   The problem therefore is to define the wtbarr struct within fitsio.h without including wcs.h, especially noting that wcs.h will often (but not always) be included together with fitsio.h in an applications program that uses **fits_read_wcstab**().

   The solution adopted is for WCSLIB to define "struct wtbarr" while fitsio.h defines "typedef wtbarr" as an untagged struct with identical members. This allows both wcs.h and fitsio.h to define a wtbarr data type without conflict by virtue of the fact that structure tags and typedef names share different name spaces in C; Appendix A, Sect. A11.1 (p227) of the K&R ANSI edition states that:

   ```
   Identifiers fall into several name spaces that do not interfere with
   one another; the same identifier may be used for different purposes,
   even in the same scope, if the uses are in different name spaces.
   These classes are: objects, functions, typedef names, and enum
   constants; labels; tags of structures, unions, and enumerations; and
   members of each structure or union individually.
   ```

   Therefore, declarations within WCSLIB look like

   ```
   struct wtbarr *w;
   ```

   while within CFITSIO they are simply

   ```
   wtbarr *w;
   ```

   As suggested by the commonality of the names, these are really the same aggregate data type. However, in passing a (struct wtbarr *) to **fits_read_wcstab**() a cast to (wtbarr *) is formally required.

   When using WCSLIB and CFITSIO together in C++ the situation is complicated by the fact that typedefs and structs share the same namespace; C++ Annotated Reference Manual, Sect. 7.1.3 (p105). In that case the wtbarr struct in wcs.h is renamed by preprocessor macro substitution to wtbarr_s to distinguish it from the typedef defined in fitsio.h. However, the scope of this macro substitution is limited to wcs.h itself and CFITSIO programmer code, whether in C++ or C, should always use the wtbarr typedef.

00041 *
00042 * fits_read_wcstab() - FITS 'TAB' table reading routine
00043 * ----------------------------------------------------
00044 * fits_read_wcstab() extracts arrays from a binary table required in
00045 * constructing 'TAB' coordinates.
00046 *
00047 * Given:
00048 *   fptr      fitsfile *
00049 *                       Pointer to the file handle returned, for example, by
00050 *                       the fits_open_file() routine in CFITSIO.
00051 *
00052 *   nwtb      int       Number of arrays to be read from the binary table(s).
00053 *
00054 * Given and returned:
00055 *   wtb       wtbarr *  Address of the first element of an array of wtbarr
00056 *                       typedefs.  This wtbarr typedef is defined to match the
00057 *                       wtbarr struct defined in WCSLIB.  An array of such
00058 *                       structs returned by the WCSLIB function wcstab() as
00059 *                       discussed in the notes below.
00060 *
00061 * Returned:
00062 *   status    int *     CFITSIO status value.
00063 *
00064 * Function return value:
00065 *             int       CFITSIO status value.
00066 *
00067 * Notes:
00068 *   1: In order to maintain WCSLIB and CFITSIO as independent libraries it is
00069 *      not permissible for any CFITSIO library code to include WCSLIB header
00070 *      files, or vice versa.  However, the CFITSIO function fits_read_wcstab()
00071 *      accepts an array of wtbarr structs defined in wcs.h within WCSLIB.
00072 *
00073 *      The problem therefore is to define the wtbarr struct within fitsio.h
00074 *      without including wcs.h, especially noting that wcs.h will often (but
00075 *      not always) be included together with fitsio.h in an applications
00076 *      program that uses fits_read_wcstab().
00077 *
00078 *      The solution adopted is for WCSLIB to define "struct wtbarr" while
00079 *      fitsio.h defines "typedef wtbarr" as an untagged struct with identical
00080 *      members.  This allows both wcs.h and fitsio.h to define a wtbarr data
00081 *      type without conflict by virtue of the fact that structure tags and
00082 *      typedef names share different name spaces in C; Appendix A, Sect. A11.1
00083 *      (p227) of the K&R ANSI edition states that:
00084 *
00085 =        Identifiers fall into several name spaces that do not interfere with
00086 =        one another; the same identifier may be used for different purposes,
00087 =        even in the same scope, if the uses are in different name spaces.
00088 =        These classes are: objects, functions, typedef names, and enum
00089 =        constants; labels; tags of structures, unions, and enumerations; and
00090 =        members of each structure or union individually.
00091 *
00092 *      Therefore, declarations within WCSLIB look like
00093 *
00094 =        struct wtbarr *w;
00095 *
00096 *      while within CFITSIO they are simply
00097 *
00098 =        wtbarr *w;
00099 *
00100 *      As suggested by the commonality of the names, these are really the same
00101 *      aggregate data type.  However, in passing a (struct wtbarr *) to
00102 *      fits_read_wcstab() a cast to (wtbarr *) is formally required.
00103 *
00104 *      When using WCSLIB and CFITSIO together in C++ the situation is
00105 *      complicated by the fact that typedefs and structs share the same
00106 *      namespace; C++ Annotated Reference Manual, Sect. 7.1.3 (p105).  In that
00107 *      case the wtbarr struct in wcs.h is renamed by preprocessor macro
00108 *      substitution to wtbarr_s to distinguish it from the typedef defined in
00109 *      fitsio.h.  However, the scope of this macro substitution is limited to
00110 *      wcs.h itself and CFITSIO programmer code, whether in C++ or C, should
00111 *      always use the wtbarr typedef.
00112 *
00113 *
00114 * wtbarr typedef
00115 * --------------
```

```
00116 * The wtbarr typedef is defined as a struct containing the following members:
00117 *
00118 *   int i
00119 *     Image axis number.
00120 *
00121 *   int m
00122 *     Array axis number for index vectors.
00123 *
00124 *   int kind
00125 *     Character identifying the array type:
00126 *       - c: coordinate array,
00127 *       - i: index vector.
00128 *
00129 *   char extnam[72]
00130 *     EXTNAME identifying the binary table extension.
00131 *
00132 *   int extver
00133 *     EXTVER identifying the binary table extension.
00134 *
00135 *   int extlev
00136 *     EXTLEV identifying the binary table extension.
00137 *
00138 *   char ttype[72]
00139 *     TTYPEn identifying the column of the binary table that contains the
00140 *     array.
00141 *
00142 *   long row
00143 *     Table row number.
00144 *
00145 *   int ndim
00146 *     Expected dimensionality of the array.
00147 *
00148 *   int *dimlen
00149 *     Address of the first element of an array of int of length ndim into
00150 *     which the array axis lengths are to be written.
00151 *
00152 *   double **arrayp
00153 *     Pointer to an array of double which is to be allocated by the user
00154 *     and into which the array is to be written.
00155 *
00156 *============================================================================*/

  Compute measures of distortion.
- int matinv (int n, const double mat[ ], double inv[ ])

  Matrix inversion.

Variables

- const char * lin_errmsg [ ]

  Status return messages.

6.9.1 Detailed Description

Routines in this suite apply the linear transformation defined by the FITS World Coordinate System (WCS) standard, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
```

These routines are based on the linprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Six routines, linini(), lininit(), lindis(), lindist() lincpy(), and linfree() are provided to manage the linprm struct, linsize() computes its total size including allocated memory, and linprt() prints its contents.

linperr() prints the error message(s) (if any) stored in a linprm struct, and the disprm structs that it may contain.

A setup routine, linset(), computes intermediate values in the linprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by linset() but need not be called explicitly - refer to the explanation of linprm::flag.

linp2x() and linx2p() implement the WCS linear transformations.

An auxiliary routine, linwarp(), computes various measures of the distortion over a specified range of pixel coordinates.

An auxiliary matrix inversion routine, matinv(), is included. It uses LU-triangular factorization with scaled partial pivoting.

6.9.2 Macro Definition Documentation

LINLEN

```
#define LINLEN (sizeof(struct linprm)/sizeof(int))
```

Size of the linprm struct in *int* units.

Size of the linprm struct in *int* units, used by the Fortran wrappers.

linini_errmsg

```
#define linini_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

lincpy_errmsg

```
#define lincpy_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

linfree_errmsg

```
#define linfree_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

linprt_errmsg

```
#define linprt_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

linset_errmsg

```
#define linset_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

linp2x_errmsg

```
#define linp2x_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

linx2p_errmsg

```
#define linx2p_errmsg lin_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use lin_errmsg directly now instead.

6.9.3 Enumeration Type Documentation

lin_errmsg_enum

```
enum lin_errmsg_enum
```

Enumerator

LINERR_SUCCESS	
LINERR_NULL_POINTER	
LINERR_MEMORY	
LINERR_SINGULAR_MTX	
LINERR_DISTORT_INIT	
LINERR_DISTORT	
LINERR_DEDISTORT	

6.9.4 Function Documentation

linini()

```
int linini (
            int alloc,
            int naxis,
            struct linprm * lin )
```

Default constructor for the linprm struct.

linini() is a thin wrapper on **lininit**(). It invokes it with ndpmax set to -1 which causes it to use the value of the global variable NDPMAX. It is thereby potentially thread-unsafe if NDPMAX is altered dynamically via disndp(). Use **lininit**() for a thread-safe alternative in this case.

lininit()

```
int lininit (
             int alloc,
             int naxis,
             struct linprm * lin,
             int ndpmax )
```

Default constructor for the linprm struct.

lininit() allocates memory for arrays in a linprm struct and sets all members of the struct to default values.

PLEASE NOTE: every linprm struct must be initialized by **lininit**(), possibly repeatedly. On the first invokation, and only the first invokation, linprm::flag must be set to -1 to initialize memory management, regardless of whether **lininit**() will actually be used to allocate memory.

Parameters

in	*alloc*	If true, allocate memory unconditionally for arrays in the linprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	*naxis*	The number of world coordinate axes, used to determine array sizes.
in,out	*lin*	Linear transformation parameters. Note that, in order to initialize memory management linprm::flag should be set to -1 when lin is initialized for the first time (memory leaks may result if it had already been initialized).
in	*ndpmax*	The number of DPja or DQia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

lindis()

```
int lindis (
             int sequence,
             struct linprm * lin,
             struct disprm * dis )
```

Assign a distortion to a linprm struct.

lindis() is a thin wrapper on **lindist**(). It invokes it with ndpmax set to -1 which causes the value of the global variable NDPMAX to be used (by disinit()). It is thereby potentially thread-unsafe if NDPMAX is altered dynamically via disndp(). Use **lindist**() for a thread-safe alternative in this case.

lindist()

```
int lindist (
            int sequence,
            struct linprm * lin,
            struct disprm * dis,
            int ndpmax )
```

Assign a distortion to a linprm struct.

lindist() may be used to assign the address of a disprm struct to linprm::dispre or linprm::disseq. The linprm struct must already have been initialized by lininit().

The disprm struct must have been allocated from the heap (e.g. using malloc(), calloc(), etc.). **lindist**() will immediately initialize it via a call to disini() using the value of linprm::naxis. Subsequently, it will be reinitialized by calls to lininit(), and freed by linfree(), neither of which would happen if the disprm struct was assigned directly.

If the disprm struct had previously been assigned via **lindist**(), it will be freed before reassignment. It is also permissable for a null disprm pointer to be assigned to disable the distortion correction.

Parameters

in	*sequence*	Is it a prior or sequent distortion? • 1: Prior, the assignment is to linprm::dispre. • 2: Sequent, the assignment is to linprm::disseq. Anything else is an error.
in,out	*lin*	Linear transformation parameters.
in,out	*dis*	Distortion function parameters.
in	*ndpmax*	The number of DPja or DQia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 4: Invalid sequence.

lincpy()

```
int lincpy (
            int alloc,
            const struct linprm * linsrc,
            struct linprm * lindst )
```

Copy routine for the linprm struct.

lincpy() does a deep copy of one linprm struct to another, using lininit() to allocate memory for its arrays if required. Only the "information to be provided" part of the struct is copied; a call to linset() is required to initialize the remainder.

Parameters

in	*alloc*	If true, allocate memory for the crpix, pc, and cdelt arrays in the destination. Otherwise, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless.
in	*linsrc*	Struct to copy from.
in,out	*lindst*	Struct to copy to. linprm::flag should be set to -1 if lindst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

linfree()

```
int linfree (
             struct linprm * lin )
```

Destructor for the linprm struct.

linfree() frees memory allocated for the linprm arrays by lininit() and/or linset(). lininit() keeps a record of the memory it allocates and **linfree**() will only attempt to free this.

PLEASE NOTE: linfree() must not be invoked on a linprm struct that was not initialized by lininit().

Parameters

in	*lin*	Linear transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.

linsize()

```
int linsize (
             const struct linprm * lin,
             int sizes[2] )
```

Compute the size of a linprm struct.

linsize() computes the full size of a linprm struct, including allocated memory.

Parameters

in	*lin*	Linear transformation parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct linprm). The second element is the total size of memory allocated in the struct, in bytes, assuming that the allocation was done by linini(). This figure includes memory allocated for members of constituent structs, such as linprm::dispre. It is not an error for the struct not to have been set up via linset(), which normally results in additional memory allocation.

Returns

Status return value:

- 0: Success.

linprt()

```
int linprt (
            const struct linprm * lin )
```

Print routine for the linprm struct.

linprt() prints the contents of a linprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*lin*	Linear transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.

linperr()

```
int linperr (
            const struct linprm * lin,
            const char * prefix )
```

Print error messages from a linprm struct.

linperr() prints the error message(s) (if any) stored in a linprm struct, and the disprm structs that it may contain. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*lin*	Coordinate transformation parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.

linset()

```
int linset (
            struct linprm * lin )
```

Setup routine for the linprm struct.

linset(), if necessary, allocates memory for the linprm::piximg and linprm::imgpix arrays and sets up the linprm struct according to information supplied within it - refer to the explanation of linprm::flag.

Note that this routine need not be called directly; it will be invoked by linp2x() and linx2p() if the linprm::flag is anything other than a predefined magic value.

Parameters

in,out	*lin*	Linear transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.
- 3: **PC**i_ja matrix is singular.
- 4: Failed to initialise distortions.

For returns $>$ 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

linp2x()

```
int linp2x (
            struct linprm * lin,
            int ncoord,
            int nelem,
            const double pixcrd[],
            double imgcrd[] )
```

Pixel-to-world linear transformation.

linp2x() transforms pixel coordinates to intermediate world coordinates.

Parameters

in,out	*lin*	Linear transformation parameters.
in	*ncoord,nelem*	The number of coordinates, each of vector length nelem but containing lin.naxis
		coordinate elements.
in	*pixcrd*	Array of pixel coordinates.
out	*imgcrd*	Array of intermediate world coordinates.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.
- 3: **PC**i_ja matrix is singular.
- 4: Failed to initialise distortions.
- 5: Distort error.

For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

Notes:
1. Historically, the API to **linp2x**() did not have a stat[] vector because a valid linear transformation should always succeed. However, now that it invokes disp2x() if distortions are present, it does have the potential to fail. Consequently, when distortions are present and a status return (stat[]) is required for each coordinate, then **linp2x**() should be invoked separately for each of them.

linx2p()

```
int linx2p (
            struct linprm * lin,
            int ncoord,
            int nelem,
            const double imgcrd[],
            double pixcrd[] )
```

World-to-pixel linear transformation.

linx2p() transforms intermediate world coordinates to pixel coordinates.

Parameters

in,out	*lin*	Linear transformation parameters.
in	*ncoord,nelem*	The number of coordinates, each of vector length nelem but containing lin.naxis coordinate elements.
in	*imgcrd*	Array of intermediate world coordinates.
out	*pixcrd*	Array of pixel coordinates. Status return value: • 0: Success. • 1: Null linprm pointer passed. • 2: Memory allocation failed. • 3: **PC**i_ja matrix is singular. • 4: Failed to initialise distortions. • 6: De-distort error. For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

Notes:

1. Historically, the API to **linx2p**() did not have a stat[] vector because a valid linear transformation should always succeed. However, now that it invokes disx2p() if distortions are present, it does have the potential to fail. Consequently, when distortions are present and a status return (stat[]) is required for each coordinate, then **linx2p**() should be invoked separately for each of them.

linwarp()

```
int linwarp (
              struct linprm * lin,
              const double pixblc[],
              const double pixtrc[],
              const double pixsamp[],
              int * nsamp,
              double maxdis[],
              double * maxtot,
              double avgdis[],
              double * avgtot,
              double rmsdis[],
              double * rmstot )
```

Compute measures of distortion.

linwarp() computes various measures of the distortion over a specified range of pixel coordinates.

All distortion measures are specified as an offset in pixel coordinates, as given directly by prior distortions. The offset in intermediate pixel coordinates given by sequent distortions is translated back to pixel coordinates by applying the inverse of the linear transformation matrix (**PC**i_ja or **CD**i_ja). The difference may be significant if the matrix introduced a scaling.

If all distortions are prior, then **linwarp**() uses diswarp(), q.v.

Parameters

in,out	*lin*	Linear transformation parameters plus distortions.
in	*pixblc*	Start of the range of pixel coordinates (i.e. "bottom left-hand corner" in the conventional FITS image display orientation). May be specified as a NULL pointer which is interpreted as (1,1,...).
in	*pixtrc*	End of the range of pixel coordinates (i.e. "top right-hand corner" in the conventional FITS image display orientation).
in	*pixsamp*	If positive or zero, the increment on the particular axis, starting at pixblc[]. Zero is interpreted as a unit increment. pixsamp may also be specified as a NULL pointer which is interpreted as all zeroes, i.e. unit increments on all axes. If negative, the grid size on the particular axis (the absolute value being rounded to the nearest integer). For example, if pixsamp is (-128.0,-128.0,...) then each axis will be sampled at 128 points between pixblc[] and pixtrc[] inclusive. Use caution when using this option on non-square images.
out	*nsamp*	The number of pixel coordinates sampled. Can be specified as a NULL pointer if not required.
out	*maxdis*	For each individual distortion function, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	*maxtot*	For the combination of all distortion functions, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	*avgdis*	For each individual distortion function, the mean value of the distortion. Can be specified as a NULL pointer if not required.

Parameters

out	*avgtot*	For the combination of all distortion functions, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	*rmsdis*	For each individual distortion function, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.
out	*rmstot*	For the combination of all distortion functions, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid parameter.
- 4: Distort error.

matinv()

```
matinv (
            int n,
            const double mat[],
            double inv[] )
```

Matrix inversion.

matinv() performs matrix inversion using LU-triangular factorization with scaled partial pivoting.

Parameters

in	*n*	Order of the matrix ($n \times n$).
in	*mat*	Matrix to be inverted, stored as mat[$in + j$] where i and j are the row and column indices respectively.
out	*inv*	Inverse of mat with the same storage convention.

Returns

Status return value:

- 0: Success.
- 2: Memory allocation failed.
- 3: Singular matrix.

6.9.5 Variable Documentation

lin_errmsg

```
const char * lin_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the lin routines
00031 * ---------------------------
00032 * Routines in this suite apply the linear transformation defined by the FITS
00033 * World Coordinate System (WCS) standard, as described in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 *
00038 * These routines are based on the linprm struct which contains all information
00039 * needed for the computations.  The struct contains some members that must be
00040 * set by the user, and others that are maintained by these routines, somewhat
00041 * like a C++ class but with no encapsulation.
00042 *
00043 * Six routines, linini(), lininit(), lindis(), lindist() lincpy(), and
00044 * linfree() are provided to manage the linprm struct, linsize() computes its
00045 * total size including allocated memory, and linprt() prints its contents.
00046 *
00047 * linperr() prints the error message(s) (if any) stored in a linprm struct,
00048 * and the disprm structs that it may contain.
00049 *
00050 * A setup routine, linset(), computes intermediate values in the linprm struct
00051 * from parameters in it that were supplied by the user.  The struct always
00052 * needs to be set up by linset() but need not be called explicitly - refer to
00053 * the explanation of linprm::flag.
00054 *
00055 * linp2x() and linx2p() implement the WCS linear transformations.
00056 *
00057 * An auxiliary routine, linwarp(), computes various measures of the distortion
00058 * over a specified range of pixel coordinates.
00059 *
00060 * An auxiliary matrix inversion routine, matinv(), is included.  It uses
00061 * LU-triangular factorization with scaled partial pivoting.
00062 *
00063 *
00064 * linini() - Default constructor for the linprm struct
00065 * ----------------------------------------------------
00066 * linini() is a thin wrapper on lininit().  It invokes it with ndpmax set
00067 * to -1 which causes it to use the value of the global variable NDPMAX.  It
00068 * is thereby potentially thread-unsafe if NDPMAX is altered dynamically via
00069 * disndp().  Use lininit() for a thread-safe alternative in this case.
00070 *
00071 *
00072 * lininit() - Default constructor for the linprm struct
00073 * -----------------------------------------------------
00074 * lininit() allocates memory for arrays in a linprm struct and sets all
```

```
00075 * members of the struct to default values.
00076 *
00077 * PLEASE NOTE: every linprm struct must be initialized by lininit(), possibly
00078 * repeatedly.  On the first invokation, and only the first invokation,
00079 * linprm::flag must be set to -1 to initialize memory management, regardless
00080 * of whether lininit() will actually be used to allocate memory.
00081 *
00082 * Given:
00083 *   alloc     int       If true, allocate memory unconditionally for arrays in
00084 *                       the linprm struct.
00085 *
00086 *                       If false, it is assumed that pointers to these arrays
00087 *                       have been set by the user except if they are null
00088 *                       pointers in which case memory will be allocated for
00089 *                       them regardless.  (In other words, setting alloc true
00090 *                       saves having to initalize these pointers to zero.)
00091 *
00092 *   naxis     int       The number of world coordinate axes, used to determine
00093 *                       array sizes.
00094 *
00095 * Given and returned:
00096 *   lin       struct linprm*
00097 *                       Linear transformation parameters.  Note that, in order
00098 *                       to initialize memory management linprm::flag should be
00099 *                       set to -1 when lin is initialized for the first time
00100 *                       (memory leaks may result if it had already been
00101 *                       initialized).
00102 *
00103 * Given:
00104 *   ndpmax    int       The number of DPja or DQia keywords to allocate space
00105 *                       for.  If set to -1, the value of the global variable
00106 *                       NDPMAX will be used.  This is potentially
00107 *                       thread-unsafe if disndp() is being used dynamically to
00108 *                       alter its value.
00109 *
00110 * Function return value:
00111 *             int       Status return value:
00112 *                         0: Success.
00113 *                         1: Null linprm pointer passed.
00114 *                         2: Memory allocation failed.
00115 *
00116 *                       For returns > 1, a detailed error message is set in
00117 *                       linprm::err if enabled, see wcserr_enable().
00118 *
00119 *
00120 * lindis() - Assign a distortion to a linprm struct
00121 * ------------------------------------------------
00122 * lindis() is a thin wrapper on lindist().   It invokes it with ndpmax set
00123 * to -1 which causes the value of the global variable NDPMAX to be used (by
00124 * disinit()).  It is thereby potentially thread-unsafe if NDPMAX is altered
00125 * dynamically via disndp().  Use lindist() for a thread-safe alternative in
00126 * this case.
00127 *
00128 *
00129 * lindist() - Assign a distortion to a linprm struct
00130 * -------------------------------------------------
00131 * lindist() may be used to assign the address of a disprm struct to
00132 * linprm::dispre or linprm::disseq.  The linprm struct must already have been
00133 * initialized by lininit().
00134 *
00135 * The disprm struct must have been allocated from the heap (e.g. using
00136 * malloc(), calloc(), etc.).  lindist() will immediately initialize it via a
00137 * call to disini() using the value of linprm::naxis.  Subsequently, it will be
00138 * reinitialized by calls to lininit(), and freed by linfree(), neither of
00139 * which would happen if the disprm struct was assigned directly.
00140 *
00141 * If the disprm struct had previously been assigned via lindist(), it will be
00142 * freed before reassignment.  It is also permissable for a null disprm pointer
00143 * to be assigned to disable the distortion correction.
00144 *
00145 * Given:
00146 *   sequence  int       Is it a prior or sequent distortion?
00147 *                         1: Prior,   the assignment is to linprm::dispre.
00148 *                         2: Sequent, the assignment is to linprm::disseq.
00149 *
00150 *                       Anything else is an error.
00151 *
00152 * Given and returned:
00153 *   lin       struct linprm*
00154 *                       Linear transformation parameters.
00155 *
00156 *   dis       struct disprm*
00157 *                       Distortion function parameters.
00158 *
00159 * Given:
00160 *   ndpmax    int       The number of DPja or DQia keywords to allocate space
00161 *                       for.  If set to -1, the value of the global variable
```

```
00162 *                       NDPMAX will be used.  This is potentially
00163 *                       thread-unsafe if disndp() is being used dynamically to
00164 *                       alter its value.
00165 *
00166 * Function return value:
00167 *             int       Status return value:
00168 *                         0: Success.
00169 *                         1: Null linprm pointer passed.
00170 *                         4: Invalid sequence.
00171 *
00172 *
00173 * lincpy() - Copy routine for the linprm struct
00174 * --------------------------------------------
00175 * lincpy() does a deep copy of one linprm struct to another, using lininit()
00176 * to allocate memory for its arrays if required.  Only the "information to be
00177 * provided" part of the struct is copied; a call to linset() is required to
00178 * initialize the remainder.
00179 *
00180 * Given:
00181 *   alloc     int       If true, allocate memory for the crpix, pc, and cdelt
00182 *                       arrays in the destination.  Otherwise, it is assumed
00183 *                       that pointers to these arrays have been set by the
00184 *                       user except if they are null pointers in which case
00185 *                       memory will be allocated for them regardless.
00186 *
00187 *   linsrc    const struct linprm*
00188 *                       Struct to copy from.
00189 *
00190 * Given and returned:
00191 *   lindst    struct linprm*
00192 *                       Struct to copy to.  linprm::flag should be set to -1
00193 *                       if lindst was not previously initialized (memory leaks
00194 *                       may result if it was previously initialized).
00195 *
00196 * Function return value:
00197 *             int       Status return value:
00198 *                         0: Success.
00199 *                         1: Null linprm pointer passed.
00200 *                         2: Memory allocation failed.
00201 *
00202 *                       For returns > 1, a detailed error message is set in
00203 *                       linprm::err if enabled, see wcserr_enable().
00204 *
00205 *
00206 * linfree() - Destructor for the linprm struct
00207 * --------------------------------------------
00208 * linfree() frees memory allocated for the linprm arrays by lininit() and/or
00209 * linset().  lininit() keeps a record of the memory it allocates and linfree()
00210 * will only attempt to free this.
00211 *
00212 * PLEASE NOTE: linfree() must not be invoked on a linprm struct that was not
00213 * initialized by lininit().
00214 *
00215 * Given:
00216 *   lin       struct linprm*
00217 *                       Linear transformation parameters.
00218 *
00219 * Function return value:
00220 *             int       Status return value:
00221 *                         0: Success.
00222 *                         1: Null linprm pointer passed.
00223 *
00224 *
00225 * linsize() - Compute the size of a linprm struct
00226 * ----------------------------------------------
00227 * linsize() computes the full size of a linprm struct, including allocated
00228 * memory.
00229 *
00230 * Given:
00231 *   lin       const struct linprm*
00232 *                       Linear transformation parameters.
00233 *
00234 *                       If NULL, the base size of the struct and the allocated
00235 *                       size are both set to zero.
00236 *
00237 * Returned:
00238 *   sizes     int[2]    The first element is the base size of the struct as
00239 *                       returned by sizeof(struct linprm).
00240 *
00241 *                       The second element is the total size of memory
00242 *                       allocated in the struct, in bytes, assuming that the
00243 *                       allocation was done by linini().  This figure includes
00244 *                       memory allocated for members of constituent structs,
00245 *                       such as linprm::dispre.
00246 *
00247 *                       It is not an error for the struct not to have been set
00248 *                       up via linset(), which normally results in additional
```

```
00249 *                       memory allocation.
00250 *
00251 * Function return value:
00252 *             int       Status return value:
00253 *                         0: Success.
00254 *
00255 *
00256 * linprt() - Print routine for the linprm struct
00257 * ---------------------------------------------
00258 * linprt() prints the contents of a linprm struct using wcsprintf().  Mainly
00259 * intended for diagnostic purposes.
00260 *
00261 * Given:
00262 *   lin       const struct linprm*
00263 *                       Linear transformation parameters.
00264 *
00265 * Function return value:
00266 *             int       Status return value:
00267 *                         0: Success.
00268 *                         1: Null linprm pointer passed.
00269 *
00270 *
00271 * linperr() - Print error messages from a linprm struct
00272 * ----------------------------------------------------
00273 * linperr() prints the error message(s) (if any) stored in a linprm struct,
00274 * and the disprm structs that it may contain.  If there are no errors then
00275 * nothing is printed.  It uses wcserr_prt(), q.v.
00276 *
00277 * Given:
00278 *   lin       const struct linprm*
00279 *                       Coordinate transformation parameters.
00280 *
00281 *   prefix    const char *
00282 *                       If non-NULL, each output line will be prefixed with
00283 *                       this string.
00284 *
00285 * Function return value:
00286 *             int       Status return value:
00287 *                         0: Success.
00288 *                         1: Null linprm pointer passed.
00289 *
00290 *
00291 * linset() - Setup routine for the linprm struct
00292 * ---------------------------------------------
00293 * linset(), if necessary, allocates memory for the linprm::piximg and
00294 * linprm::imgpix arrays and sets up the linprm struct according to information
00295 * supplied within it - refer to the explanation of linprm::flag.
00296 *
00297 * Note that this routine need not be called directly; it will be invoked by
00298 * linp2x() and linx2p() if the linprm::flag is anything other than a
00299 * predefined magic value.
00300 *
00301 * Given and returned:
00302 *   lin       struct linprm*
00303 *                       Linear transformation parameters.
00304 *
00305 * Function return value:
00306 *             int       Status return value:
00307 *                         0: Success.
00308 *                         1: Null linprm pointer passed.
00309 *                         2: Memory allocation failed.
00310 *                         3: PCi_ja matrix is singular.
00311 *                         4: Failed to initialise distortions.
00312 *
00313 *                       For returns > 1, a detailed error message is set in
00314 *                       linprm::err if enabled, see wcserr_enable().
00315 *
00316 *
00317 * linp2x() - Pixel-to-world linear transformation
00318 * ----------------------------------------------
00319 * linp2x() transforms pixel coordinates to intermediate world coordinates.
00320 *
00321 * Given and returned:
00322 *   lin       struct linprm*
00323 *                       Linear transformation parameters.
00324 *
00325 * Given:
00326 *   ncoord,
00327 *   nelem     int       The number of coordinates, each of vector length nelem
00328 *                       but containing lin.naxis coordinate elements.
00329 *
00330 *   pixcrd    const double[ncoord][nelem]
00331 *                       Array of pixel coordinates.
00332 *
00333 * Returned:
00334 *   imgcrd    double[ncoord][nelem]
00335 *                       Array of intermediate world coordinates.
```

```
00336 *
00337 * Function return value:
00338 *             int       Status return value:
00339 *                         0: Success.
00340 *                         1: Null linprm pointer passed.
00341 *                         2: Memory allocation failed.
00342 *                         3: PCi_ja matrix is singular.
00343 *                         4: Failed to initialise distortions.
00344 *                         5: Distort error.
00345 *
00346 *                       For returns > 1, a detailed error message is set in
00347 *                       linprm::err if enabled, see wcserr_enable().
00348 *
00349 * Notes:
00350 *   1. Historically, the API to linp2x() did not have a stat[] vector because
00351 *      a valid linear transformation should always succeed.  However, now that
00352 *      it invokes disp2x() if distortions are present, it does have the
00353 *      potential to fail.  Consequently, when distortions are present and a
00354 *      status return (stat[]) is required for each coordinate, then linp2x()
00355 *      should be invoked separately for each of them.
00356 *
00357 *
00358 * linx2p() - World-to-pixel linear transformation
00359 * -----------------------------------------------
00360 * linx2p() transforms intermediate world coordinates to pixel coordinates.
00361 *
00362 * Given and returned:
00363 *   lin       struct linprm*
00364 *                       Linear transformation parameters.
00365 *
00366 * Given:
00367 *   ncoord,
00368 *   nelem     int       The number of coordinates, each of vector length nelem
00369 *                       but containing lin.naxis coordinate elements.
00370 *
00371 *   imgcrd    const double[ncoord][nelem]
00372 *                       Array of intermediate world coordinates.
00373 *
00374 * Returned:
00375 *   pixcrd    double[ncoord][nelem]
00376 *                       Array of pixel coordinates.
00377 *
00378 *             int       Status return value:
00379 *                         0: Success.
00380 *                         1: Null linprm pointer passed.
00381 *                         2: Memory allocation failed.
00382 *                         3: PCi_ja matrix is singular.
00383 *                         4: Failed to initialise distortions.
00384 *                         6: De-distort error.
00385 *
00386 *                       For returns > 1, a detailed error message is set in
00387 *                       linprm::err if enabled, see wcserr_enable().
00388 *
00389 * Notes:
00390 *   1. Historically, the API to linx2p() did not have a stat[] vector because
00391 *      a valid linear transformation should always succeed.  However, now that
00392 *      it invokes disx2p() if distortions are present, it does have the
00393 *      potential to fail.  Consequently, when distortions are present and a
00394 *      status return (stat[]) is required for each coordinate, then linx2p()
00395 *      should be invoked separately for each of them.
00396 *
00397 *
00398 * linwarp() - Compute measures of distortion
00399 * ------------------------------------------
00400 * linwarp() computes various measures of the distortion over a specified range
00401 * of pixel coordinates.
00402 *
00403 * All distortion measures are specified as an offset in pixel coordinates,
00404 * as given directly by prior distortions.  The offset in intermediate pixel
00405 * coordinates given by sequent distortions is translated back to pixel
00406 * coordinates by applying the inverse of the linear transformation matrix
00407 * (PCi_ja or CDi_ja).  The difference may be significant if the matrix
00408 * introduced a scaling.
00409 *
00410 * If all distortions are prior, then linwarp() uses diswarp(), q.v.
00411 *
00412 * Given and returned:
00413 *   lin       struct linprm*
00414 *                       Linear transformation parameters plus distortions.
00415 *
00416 * Given:
00417 *   pixblc    const double[naxis]
00418 *                       Start of the range of pixel coordinates (i.e. "bottom
00419 *                       left-hand corner" in the conventional FITS image
00420 *                       display orientation).  May be specified as a NULL
00421 *                       pointer which is interpreted as (1,1,...).
00422 *
```

```
00423 *   pixtrc    const double[naxis]
00424 *                       End of the range of pixel coordinates (i.e. "top
00425 *                       right-hand corner" in the conventional FITS image
00426 *                       display orientation).
00427 *
00428 *   pixsamp   const double[naxis]
00429 *                       If positive or zero, the increment on the particular
00430 *                       axis, starting at pixblc[].  Zero is interpreted as a
00431 *                       unit increment.  pixsamp may also be specified as a
00432 *                       NULL pointer which is interpreted as all zeroes, i.e.
00433 *                       unit increments on all axes.
00434 *
00435 *                       If negative, the grid size on the particular axis (the
00436 *                       absolute value being rounded to the nearest integer).
00437 *                       For example, if pixsamp is (-128.0,-128.0,...) then
00438 *                       each axis will be sampled at 128 points between
00439 *                       pixblc[] and pixtrc[] inclusive.  Use caution when
00440 *                       using this option on non-square images.
00441 *
00442 * Returned:
00443 *   nsamp     int*      The number of pixel coordinates sampled.
00444 *
00445 *                       Can be specified as a NULL pointer if not required.
00446 *
00447 *   maxdis    double[naxis]
00448 *                       For each individual distortion function, the
00449 *                       maximum absolute value of the distortion.
00450 *
00451 *                       Can be specified as a NULL pointer if not required.
00452 *
00453 *   maxtot    double*   For the combination of all distortion functions, the
00454 *                       maximum absolute value of the distortion.
00455 *
00456 *                       Can be specified as a NULL pointer if not required.
00457 *
00458 *   avgdis    double[naxis]
00459 *                       For each individual distortion function, the
00460 *                       mean value of the distortion.
00461 *
00462 *                       Can be specified as a NULL pointer if not required.
00463 *
00464 *   avgtot    double*   For the combination of all distortion functions, the
00465 *                       mean value of the distortion.
00466 *
00467 *                       Can be specified as a NULL pointer if not required.
00468 *
00469 *   rmsdis    double[naxis]
00470 *                       For each individual distortion function, the
00471 *                       root mean square deviation of the distortion.
00472 *
00473 *                       Can be specified as a NULL pointer if not required.
00474 *
00475 *   rmstot    double*   For the combination of all distortion functions, the
00476 *                       root mean square deviation of the distortion.
00477 *
00478 *                       Can be specified as a NULL pointer if not required.
00479 *
00480 * Function return value:
00481 *             int       Status return value:
00482 *                         0: Success.
00483 *                         1: Null linprm pointer passed.
00484 *                         2: Memory allocation failed.
00485 *                         3: Invalid parameter.
00486 *                         4: Distort error.
00487 *
00488 *
00489 * linprm struct - Linear transformation parameters
00490 * ------------------------------------------------
00491 * The linprm struct contains all of the information required to perform a
00492 * linear transformation.  It consists of certain members that must be set by
00493 * the user ("given") and others that are set by the WCSLIB routines
00494 * ("returned").
00495 *
00496 *   int flag
00497 *     (Given and returned) This flag must be set to zero whenever any of the
00498 *     following members of the linprm struct are set or modified:
00499 *
00500 *       - linprm::naxis (q.v., not normally set by the user),
00501 *       - linprm::pc,
00502 *       - linprm::cdelt,
00503 *       - linprm::dispre.
00504 *       - linprm::disseq.
00505 *
00506 *     This signals the initialization routine, linset(), to recompute the
00507 *     returned members of the linprm struct.  linset() will reset flag to
00508 *     indicate that this has been done.
00509 *
```

```
00510 *     PLEASE NOTE: flag should be set to -1 when lininit() is called for the
00511 *     first time for a particular linprm struct in order to initialize memory
00512 *     management.  It must ONLY be used on the first initialization otherwise
00513 *     memory leaks may result.
00514 *
00515 *   int naxis
00516 *     (Given or returned) Number of pixel and world coordinate elements.
00517 *
00518 *     If lininit() is used to initialize the linprm struct (as would normally
00519 *     be the case) then it will set naxis from the value passed to it as a
00520 *     function argument.  The user should not subsequently modify it.
00521 *
00522 *   double *crpix
00523 *     (Given) Pointer to the first element of an array of double containing
00524 *     the coordinate reference pixel, CRPIXja.
00525 *
00526 *     It is not necessary to reset the linprm struct (via linset()) when
00527 *     linprm::crpix is changed.
00528 *
00529 *   double *pc
00530 *     (Given) Pointer to the first element of the PCi_ja (pixel coordinate)
00531 *     transformation matrix.  The expected order is
00532 *
00533 =       struct linprm lin;
00534 =       lin.pc = {PC1_1, PC1_2, PC2_1, PC2_2};
00535 *
00536 *     This may be constructed conveniently from a 2-D array via
00537 *
00538 =       double m[2][2] = {{PC1_1, PC1_2},
00539 =                         {PC2_1, PC2_2}};
00540 *
00541 *     which is equivalent to
00542 *
00543 =       double m[2][2];
00544 =       m[0][0] = PC1_1;
00545 =       m[0][1] = PC1_2;
00546 =       m[1][0] = PC2_1;
00547 =       m[1][1] = PC2_2;
00548 *
00549 *     The storage order for this 2-D array is the same as for the 1-D array,
00550 *     whence
00551 *
00552 =       lin.pc = *m;
00553 *
00554 *     would be legitimate.
00555 *
00556 *   double *cdelt
00557 *     (Given) Pointer to the first element of an array of double containing
00558 *     the coordinate increments, CDELTia.
00559 *
00560 *   struct disprm *dispre
00561 *     (Given) Pointer to a disprm struct holding parameters for prior
00562 *     distortion functions, or a null (0x0) pointer if there are none.
00563 *
00564 *     Function lindist() may be used to assign a disprm pointer to a linprm
00565 *     struct, allowing it to take control of any memory allocated for it, as
00566 *     in the following example:
00567 *
00568 =       void add_distortion(struct linprm *lin)
00569 =       {
00570 =         struct disprm *dispre;
00571 =
00572 =         dispre = malloc(sizeof(struct disprm));
00573 =         dispre->flag = -1;
00574 =         lindist(1, lin, dispre, ndpmax);
00575 =           :
00576 =          (Set up dispre.)
00577 =           :
00578 =
00579 =         return;
00580 =       }
00581 *
00582 *     Here, after the distortion function parameters etc. are copied into
00583 *     dispre, dispre is assigned using lindist() which takes control of the
00584 *     allocated memory.  It will be freed later when linfree() is invoked on
00585 *     the linprm struct.
00586 *
00587 *     Consider also the following erroneous code:
00588 *
00589 =       void bad_code(struct linprm *lin)
00590 =       {
00591 =         struct disprm dispre;
00592 =
00593 =         dispre.flag = -1;
00594 =         lindist(1, lin, &dispre, ndpmax);   // WRONG.
00595 =           :
00596 =
```

```
00597 =         return;
00598 =       }
00599 *
00600 *     Here, dispre is declared as a struct, rather than a pointer.  When the
00601 *     function returns, dispre will go out of scope and its memory will most
00602 *     likely be reused, thereby trashing its contents.  Later, a segfault will
00603 *     occur when linfree() tries to free dispre's stale address.
00604 *
00605 *   struct disprm *disseq
00606 *     (Given) Pointer to a disprm struct holding parameters for sequent
00607 *     distortion functions, or a null (0x0) pointer if there are none.
00608 *
00609 *     Refer to the comments and examples given for disprm::dispre.
00610 *
00611 *   double *piximg
00612 *     (Returned) Pointer to the first element of the matrix containing the
00613 *     product of the CDELTia diagonal matrix and the PCi_ja matrix.
00614 *
00615 *   double *imgpix
00616 *     (Returned) Pointer to the first element of the inverse of the
00617 *     linprm::piximg matrix.
00618 *
00619 *   int i_naxis
00620 *     (Returned) The dimension of linprm::piximg and linprm::imgpix (normally
00621 *     equal to naxis).
00622 *
00623 *   int unity
00624 *     (Returned) True if the linear transformation matrix is unity.
00625 *
00626 *   int affine
00627 *     (Returned) True if there are no distortions.
00628 *
00629 *   int simple
00630 *     (Returned) True if unity and no distortions.
00631 *
00632 *   struct wcserr *err
00633 *     (Returned) If enabled, when an error status is returned, this struct
00634 *     contains detailed information about the error, see wcserr_enable().
00635 *
00636 *   double *tmpcrd
00637 *     (For internal use only.)
00638 *   int m_flag
00639 *     (For internal use only.)
00640 *   int m_naxis
00641 *     (For internal use only.)
00642 *   double *m_crpix
00643 *     (For internal use only.)
00644 *   double *m_pc
00645 *     (For internal use only.)
00646 *   double *m_cdelt
00647 *     (For internal use only.)
00648 *   struct disprm *m_dispre
00649 *     (For internal use only.)
00650 *   struct disprm *m_disseq
00651 *     (For internal use only.)
00652 *
00653 *
00654 * Global variable: const char *lin_errmsg[] - Status return messages
00655 * ---------------------------------------------------------------
00656 * Error messages to match the status value returned from each function.
00657 *
00658 *===========================================================================*/

6.11 log.h File Reference

Enumerations

- enum log_errmsg_enum {
  LOGERR_SUCCESS = 0 , LOGERR_NULL_POINTER = 1 , LOGERR_BAD_LOG_REF_VAL = 2 ,
  LOGERR_BAD_X = 3 ,
  LOGERR_BAD_WORLD = 4 }

Functions

- int logx2s (double crval, int nx, int sx, int slogc, const double x[ ], double logc[ ], int stat[ ])

  Transform to logarithmic coordinates.
- int logs2x (double crval, int nlogc, int slogc, int sx, const double logc[ ], double x[ ], int stat[ ])

  Transform logarithmic coordinates.

Variables

- const char ∗ log_errmsg [ ]

  Status return messages.

6.11.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with logarithmic coordinates, as described in

"Representations of world coordinates in FITS", Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of spectral coordinates in FITS", Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L. 2006, A&A, 446, 747 (WCS Paper III)

These routines define methods to be used for computing logarithmic world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa.

logx2s() and logs2x() implement the WCS logarithmic coordinate transformations.

Argument checking:
The input log-coordinate values are only checked for values that would result in floating point exceptions and the same is true for the log-coordinate reference value.

Accuracy:
No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine tlog.c which accompanies this software.

6.11.2 Enumeration Type Documentation

log_errmsg_enum

```
enum log_errmsg_enum
```

Enumerator

LOGERR_SUCCESS	
LOGERR_NULL_POINTER	
LOGERR_BAD_LOG_REF_VAL	
LOGERR_BAD_X	
LOGERR_BAD_WORLD	

6.11.3 Function Documentation

logx2s()

```
int logx2s (
             double crval,
             int nx,
             int sx,
             int slogc,
             const double x[],
             double logc[],
             int stat[] )
```

Transform to logarithmic coordinates.

logx2s() transforms intermediate world coordinates to logarithmic coordinates.

Parameters

in,out	*crval*	Log-coordinate reference value (**CRVAL**ia).
in	*nx*	Vector length.
in	*sx*	Vector stride.
in	*slogc*	Vector stride.
in	*x*	Intermediate world coordinates, in SI units.
out	*logc*	Logarithmic coordinates, in SI units.
out	*stat*	Status return value status for each vector element: • 0: Success.

Returns

Status return value:

- 0: Success.
- 2: Invalid log-coordinate reference value.

logs2x()

```
int logs2x (
             double crval,
```

```
            int nlogc,
            int slogc,
            int sx,
            const double logc[],
            double x[],
            int stat[] )
```

Transform logarithmic coordinates.

logs2x() transforms logarithmic world coordinates to intermediate world coordinates.

Parameters

in,out	*crval*	Log-coordinate reference value (**CRVAL**ia).
in	*nlogc*	Vector length.
in	*slogc*	Vector stride.
in	*sx*	Vector stride.
in	*logc*	Logarithmic coordinates, in SI units.
out	*x*	Intermediate world coordinates, in SI units.
out	*stat*	Status return value status for each vector element: • 0: Success. • 1: Invalid value of logc.

Returns

Status return value:

- 0: Success.
- 2: Invalid log-coordinate reference value.
- 4: One or more of the world-coordinate values are incorrect, as indicated by the stat vector.

6.11.4 Variable Documentation

log_errmsg

```
const char * log_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

- int hpxs2x (PRJS2X_ARGS)

  *Spherical-to-Cartesian transformation for the **HEALPix (HPX)** projection.*

- int xphset (struct prjprm *prj)
- int xphx2s (PRJX2S_ARGS)
- int xphs2x (PRJS2X_ARGS)

Variables

- const char * prj_errmsg [ ]

  Status return messages.

- const int CONIC

  Identifier for conic projections.

- const int CONVENTIONAL

  Identifier for conventional projections.

- const int CYLINDRICAL

  Identifier for cylindrical projections.

- const int POLYCONIC

  Identifier for polyconic projections.

- const int PSEUDOCYLINDRICAL

  Identifier for pseudocylindrical projections.

- const int QUADCUBE

  Identifier for quadcube projections.

- const int ZENITHAL

  Identifier for zenithal/azimuthal projections.

- const int HEALPIX

  Identifier for the HEALPix projection.

- const char prj_categories [9][32]

  Projection categories.

- const int prj_ncode

  The number of recognized three-letter projection codes.

- const char prj_codes [28][4]

  Recognized three-letter projection codes.

6.13.1 Detailed Description

Routines in this suite implement the spherical map projections defined by the FITS World Coordinate System (WCS) standard, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Mapping on the HEALPix grid",
Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865 (WCS Paper V)

"Representing the 'Butterfly' Projection in FITS -- Projection Code XPH",
Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050 (WCS Paper VI)
```

These routines are based on the prjprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Routine prjini() is provided to initialize the prjprm struct with default values, prjfree() reclaims any memory that may have been allocated to store an error message, prjsize() computes its total size including allocated memory, and prjprt() prints its contents.

prjperr() prints the error message(s) (if any) stored in a prjprm struct. prjbchk() performs bounds checking on native spherical coordinates.

Setup routines for each projection with names of the form **???set()**, where "???" is the down-cased three-letter projection code, compute intermediate values in the prjprm struct from parameters in it that were supplied by the user. The struct always needs to be set by the projection's setup routine but that need not be called explicitly - refer to the explanation of prjprm::flag.

Each map projection is implemented via separate functions for the spherical projection, **???s2x()**, and deprojection, **???x2s()**.

A set of driver routines, prjset(), prjx2s(), and prjs2x(), provides a generic interface to the specific projection routines which they invoke via pointers-to-functions stored in the prjprm struct.

In summary, the routines are:

- prjini() Initialization routine for the prjprm struct.
- prjfree() Reclaim memory allocated for error messages.
- prjsize() Compute total size of a prjprm struct.
- prjprt() Print a prjprm struct.
- prjperr() Print error message (if any).
- prjbchk() Bounds checking on native coordinates.
- prjset(), prjx2s(), prjs2x(): Generic driver routines
- azpset(), azpx2s(), azps2x(): **AZP** (zenithal/azimuthal perspective)
- szpset(), szpx2s(), szps2x(): **SZP** (slant zenithal perspective)
- tanset(), tanx2s(), tans2x(): **TAN** (gnomonic)
- stgset(), stgx2s(), stgs2x(): **STG** (stereographic)
- sinset(), sinx2s(), sins2x(): **SIN** (orthographic/synthesis)
- arcset(), arcx2s(), arcs2x(): **ARC** (zenithal/azimuthal equidistant)
- zpnset(), zpnx2s(), zpns2x(): **ZPN** (zenithal/azimuthal polynomial)
- zeaset(), zeax2s(), zeas2x(): **ZEA** (zenithal/azimuthal equal area)
- airset(), airx2s(), airs2x(): **AIR** (Airy)
- cypset(), cypx2s(), cyps2x(): **CYP** (cylindrical perspective)
- ceaset(), ceax2s(), ceas2x(): **CEA** (cylindrical equal area)
- carset(), carx2s(), cars2x(): **CAR** (Plate carée)
- merset(), merx2s(), mers2x(): **MER** (Mercator)

- sflset(), sflx2s(), sfls2x(): **SFL** (Sanson-Flamsteed)
- parset(), parx2s(), pars2x(): **PAR** (parabolic)
- molset(), molx2s(), mols2x(): **MOL** (Mollweide)
- aitset(), aitx2s(), aits2x(): **AIT** (Hammer-Aitoff)
- copset(), copx2s(), cops2x(): **COP** (conic perspective)
- coeset(), coex2s(), coes2x(): **COE** (conic equal area)
- codset(), codx2s(), cods2x(): **COD** (conic equidistant)
- cooset(), coox2s(), coos2x(): **COO** (conic orthomorphic)
- bonset(), bonx2s(), bons2x(): **BON** (Bonne)
- pcoset(), pcox2s(), pcos2x(): **PCO** (polyconic)
- tscset(), tscx2s(), tscs2x(): **TSC** (tangential spherical cube)
- cscset(), cscx2s(), cscs2x(): **CSC** (COBE spherical cube)
- qscset(), qscx2s(), qscs2x(): **QSC** (quadrilateralized spherical cube)
- hpxset(), hpxx2s(), hpxs2x(): **HPX** (HEALPix)
- xphset(), xphx2s(), xphs2x(): XPH (HEALPix polar, aka "butterfly")

Argument checking (projection routines):
The values of ϕ and θ (the native longitude and latitude) normally lie in the range $[-180°, 180°]$ for ϕ, and $[-90°, 90°]$ for θ. However, all projection routines will accept any value of ϕ and will not normalize it.

The projection routines do not explicitly check that θ lies within the range $[-90°, 90°]$. They do check for any value of θ that produces an invalid argument to the projection equations (e.g. leading to division by zero). The projection routines for **AZP**, **SZP**, **TAN**, **SIN**, **ZPN**, and **COP** also return error 2 if (ϕ, θ) corresponds to the overlapped (far) side of the projection but also return the corresponding value of (x, y). This strict bounds checking may be relaxed at any time by setting prjprm::bounds%2 to 0 (rather than 1); the projections need not be reinitialized.

Argument checking (deprojection routines):
Error checking on the projected coordinates (x, y) is limited to that required to ascertain whether a solution exists. Where a solution does exist, an optional check is made that the value of ϕ and θ obtained lie within the ranges $[-180°, 180°]$ for ϕ, and $[-90°, 90°]$ for θ. This check, performed by prjbchk(), is enabled by default. It may be disabled by setting prjprm::bounds%4 to 0 (rather than 1); the projections need not be reinitialized.

Accuracy:
No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure to a precision of at least $0°.0000000001$ of longitude and latitude has been verified for typical projection parameters on the $1°$ degree graticule of native longitude and latitude (to within $5°$ of any latitude where the projection may diverge). Refer to the tprj1.c and tprj2.c test routines that accompany this software.

6.13.2 Macro Definition Documentation

PVN

```
#define PVN 30
```

Total number of projection parameters.

The total number of projection parameters numbered 0 to **PVN**-1.

PRJX2S_ARGS

```
#define PRJX2S_ARGS
```

Value:

```
struct prjprm *prj, int nx, int ny, int sxy, int spt, \
const double x[], const double y[], double phi[], double theta[], int stat[]
```

For use in declaring deprojection function prototypes.

Preprocessor macro used for declaring deprojection function prototypes.

PRJS2X_ARGS

```
#define PRJS2X_ARGS
```

Value:

```
struct prjprm *prj, int nx, int ny, int sxy, int spt, \
const double phi[], const double theta[], double x[], double y[], int stat[]
```

For use in declaring projection function prototypes.

Preprocessor macro used for declaring projection function prototypes.

PRJLEN

```
#define PRJLEN (sizeof(struct prjprm)/sizeof(int))
```

Size of the prjprm struct in *int* units.

Size of the prjprm struct in *int* units, used by the Fortran wrappers.

prjini_errmsg

```
#define prjini_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjprt_errmsg

```
#define prjprt_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjset_errmsg

```
#define prjset_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjx2s_errmsg

```
#define prjx2s_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjs2x_errmsg

```
#define prjs2x_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

6.13.3 Enumeration Type Documentation

prj_errmsg_enum

```
enum prj_errmsg_enum
```

Enumerator

PRJERR_SUCCESS	
PRJERR_NULL_POINTER	
PRJERR_BAD_PARAM	
PRJERR_BAD_PIX	
PRJERR_BAD_WORLD	

6.13.4 Function Documentation

prjini()

```
int prjini (
            struct prjprm * prj )
```

Default constructor for the prjprm struct.

prjini() sets all members of a prjprm struct to default values. It should be used to initialize every prjprm struct.

PLEASE NOTE: If the prjprm struct has already been initialized, then before reinitializing, it prjfree() should be used to free any memory that may have been allocated to store an error message. A memory leak may otherwise result.

Parameters

out	*prj*	Projection parameters.

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjfree()

```
int prjfree (
             struct prjprm * prj )
```

Destructor for the prjprm struct.

prjfree() frees any memory that may have been allocated to store an error message in the prjprm struct.

Parameters

in	*prj*	Projection parameters.

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjsize()

```
int prjsize (
             const struct prjprm * prj,
             int sizes[2] )
```

Compute the size of a prjprm struct.

prjsize() computes the full size of a prjprm struct, including allocated memory.

Parameters

in	*prj*	Projection parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct prjprm). The second element is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct, prjprm::err. It is not an error for the struct not to have been set up via prjset().

Returns

Status return value:

- 0: Success.

prjprt()

```
int prjprt (
            const struct prjprm * prj )
```

Print routine for the prjprm struct.

prjprt() prints the contents of a prjprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*prj*	Projection parameters.

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjperr()

```
int prjperr (
            const struct prjprm * prj,
            const char * prefix )
```

Print error messages from a prjprm struct.

prjperr() prints the error message(s) (if any) stored in a prjprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*prj*	Projection parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjbchk()

```
int prjbchk (
             double tol,
             int nphi,
             int ntheta,
             int spt,
             double phi[],
             double theta[],
             int stat[] )
```

Bounds checking on native coordinates.

prjbchk() performs bounds checking on native spherical coordinates. As returned by the deprojection (x2s) routines, native longitude is expected to lie in the closed interval $[-180°, 180°]$, with latitude in $[-90°, 90°]$.

A tolerance may be specified to provide a small allowance for numerical imprecision. Values that lie outside the allowed range by not more than the specified tolerance will be adjusted back into range.

If prjprm::bounds&4 is set, as it is by prjini(), then **prjbchk**() will be invoked automatically by the Cartesian-to-spherical deprojection (x2s) routines with an appropriate tolerance set for each projection.

Parameters

in	*tol*	Tolerance for the bounds check [deg].
in	*nphi,ntheta*	Vector lengths.
in	*spt*	Vector stride.
in,out	*phi,theta*	Native longitude and latitude (ϕ, θ) [deg].
out	*stat*	Status value for each vector element: • 0: Valid value of (ϕ, θ). • 1: Invalid value.

Returns

Status return value:

- 0: Success.
- 1: One or more of the (ϕ, θ) coordinates were, invalid, as indicated by the stat vector.

prjset()

```
int prjset (
             struct prjprm * prj )
```

Generic setup routine for the prjprm struct.

prjset() sets up a prjprm struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by prjx2s() and prjs2x() if prj.flag is anything other than a predefined magic value.

The one important distinction between **prjset**() and the setup routines for the specific projections is that the projection code must be defined in the prjprm struct in order for **prjset**() to identify the required projection. Once **prjset**() has initialized the prjprm struct, prjx2s() and prjs2x() use the pointers to the specific projection and deprojection routines contained therein.

Parameters

in,out	*prj*	Projection parameters.

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.
- 2: Invalid projection parameters.

For returns $>$ 1, a detailed error message is set in prjprm::err if enabled, see wcserr_enable().

prjx2s()

```
int prjx2s (
              PRJX2S_ARGS  )
```

Generic Cartesian-to-spherical deprojection.

Deproject Cartesian (x, y) coordinates in the plane of projection to native spherical coordinates (ϕ, θ).

The projection is that specified by prjprm::code.

Parameters

in,out	*prj*	Projection parameters.
in	*nx,ny*	Vector lengths.
in	*sxy,spt*	Vector strides.
in	*x,y*	Projected coordinates.
out	*phi,theta*	Longitude and latitude (ϕ, θ) of the projected point in native spherical coordinates [deg].
out	*stat*	Status value for each vector element: • 0: Success. • 1: Invalid value of (x, y).

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.
- 2: Invalid projection parameters.
- 3: One or more of the (x, y) coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in prjprm::err if enabled, see wcserr_enable().

prjs2x()

```
int prjs2x (
            PRJS2X_ARGS  )
```

Generic spherical-to-Cartesian projection.

Project native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of projection.

The projection is that specified by prjprm::code.

Parameters

in,out	*prj*	Projection parameters.
in	*nphi,ntheta*	Vector lengths.
in	*spt,sxy*	Vector strides.
in	*phi,theta*	Longitude and latitude (ϕ, θ) of the projected point in native spherical coordinates [deg].
out	*x,y*	Projected coordinates.
out	*stat*	Status value for each vector element: • 0: Success. • 1: Invalid value of (ϕ, θ).

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.
- 2: Invalid projection parameters.
- 4: One or more of the (ϕ, θ) coordinates were, invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in prjprm::err if enabled, see wcserr_enable().

azpset()

```
int azpset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **zenithal/azimuthal perspective (AZP)** projection.

azpset() sets up a prjprm struct for a **zenithal/azimuthal perspective (AZP)** projection.

See prjset() for a description of the API.

azpx2s()

```
int azpx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **zenithal/azimuthal perspective (AZP)** projection.

azpx2s() deprojects Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal perspective (AZP)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

azps2x()

```
int azps2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **zenithal/azimuthal perspective (AZP)** projection.

azps2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal perspective (AZP)** projection.

See prjs2x() for a description of the API.

szpset()

```
int szpset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **slant zenithal perspective (SZP)** projection.

szpset() sets up a prjprm struct for a **slant zenithal perspective (SZP)** projection.

See prjset() for a description of the API.

szpx2s()

```
int szpx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **slant zenithal perspective (SZP)** projection.

szpx2s() deprojects Cartesian (x, y) coordinates in the plane of a **slant zenithal perspective (SZP)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

szps2x()

```
int szps2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **slant zenithal perspective (SZP)** projection.

szps2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **slant zenithal perspective (SZP)** projection.

See prjs2x() for a description of the API.

tanset()

```
int tanset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **gnomonic (TAN)** projection.

tanset() sets up a prjprm struct for a **gnomonic (TAN)** projection.

See prjset() for a description of the API.

tanx2s()

```
int tanx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **gnomonic (TAN)** projection.

tanx2s() deprojects Cartesian (x, y) coordinates in the plane of a **gnomonic (TAN)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

tans2x()

```
int tans2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **gnomonic (TAN)** projection.

tans2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **gnomonic (TAN)** projection.

See prjs2x() for a description of the API.

stgset()

```
int stgset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **stereographic (STG)** projection.

stgset() sets up a prjprm struct for a **stereographic (STG)** projection.

See prjset() for a description of the API.

stgx2s()

```
int stgx2s (
              PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **stereographic (STG)** projection.

stgx2s() deprojects Cartesian (x, y) coordinates in the plane of a **stereographic (STG)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

stgs2x()

```
int stgs2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **stereographic (STG)** projection.

stgs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **stereographic (STG)** projection.

See prjs2x() for a description of the API.

sinset()

```
int sinset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **orthographic/synthesis (SIN)** projection.

stgset() sets up a prjprm struct for an **orthographic/synthesis (SIN)** projection.

See prjset() for a description of the API.

sinx2s()

```
int sinx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **orthographic/synthesis (SIN)** projection.

sinx2s() deprojects Cartesian (x, y) coordinates in the plane of an **orthographic/synthesis (SIN)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

sins2x()

```
int sins2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **orthographic/synthesis (SIN)** projection.

sins2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of an **orthographic/synthesis (SIN)** projection.

See prjs2x() for a description of the API.

arcset()

```
int arcset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **zenithal/azimuthal equidistant (ARC)** projection.

arcset() sets up a prjprm struct for a **zenithal/azimuthal equidistant (ARC)** projection.

See prjset() for a description of the API.

arcx2s()

```
int arcx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **zenithal/azimuthal equidistant (ARC)** projection.

arcx2s() deprojects Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal equidistant (ARC)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

arcs2x()

```
int arcs2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **zenithal/azimuthal equidistant (ARC)** projection.

arcs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal equidistant (ARC)** projection.

See prjs2x() for a description of the API.

zpnset()

```
int zpnset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **zenithal/azimuthal polynomial (ZPN)** projection.

zpnset() sets up a prjprm struct for a **zenithal/azimuthal polynomial (ZPN)** projection.

See prjset() for a description of the API.

zpnx2s()

```
int zpnx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **zenithal/azimuthal polynomial (ZPN)** projection.

zpnx2s() deprojects Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal polynomial (ZPN)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

zpns2x()

```
int zpns2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **zenithal/azimuthal polynomial (ZPN)** projection.

zpns2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal polynomial (ZPN)** projection.

See prjs2x() for a description of the API.

zeaset()

```
int zeaset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **zenithal/azimuthal equal area (ZEA)** projection.

zeaset() sets up a prjprm struct for a **zenithal/azimuthal equal area (ZEA)** projection.

See prjset() for a description of the API.

zeax2s()

```
int zeax2s (
              PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **zenithal/azimuthal equal area (ZEA)** projection.

zeax2s() deprojects Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal equal area (ZEA)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

zeas2x()

```
int zeas2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **zenithal/azimuthal equal area (ZEA)** projection.

zeas2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal equal area (ZEA)** projection.

See prjs2x() for a description of the API.

airset()

```
int airset (
              struct prjprm * prj )
```

Set up a prjprm struct for **Airy's (AIR)** projection.

airset() sets up a prjprm struct for an **Airy (AIR)** projection.

See prjset() for a description of the API.

airx2s()

```
int airx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for **Airy's (AIR)** projection.

airx2s() deprojects Cartesian (x, y) coordinates in the plane of an **Airy (AIR)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

airs2x()

```
int airs2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for **Airy's (AIR)** projection.

airs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of an **Airy (AIR)** projection.

See prjs2x() for a description of the API.

cypset()

```
int cypset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **cylindrical perspective (CYP)** projection.

cypset() sets up a prjprm struct for a **cylindrical perspective (CYP)** projection.

See prjset() for a description of the API.

cypx2s()

```
int cypx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **cylindrical perspective (CYP)** projection.

cypx2s() deprojects Cartesian (x, y) coordinates in the plane of a **cylindrical perspective (CYP)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

cyps2x()

```
int cyps2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **cylindrical perspective (CYP)** projection.

cyps2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **cylindrical perspective (CYP)** projection.

See prjs2x() for a description of the API.

ceaset()

```
int ceaset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **cylindrical equal area (CEA)** projection.

ceaset() sets up a prjprm struct for a **cylindrical equal area (CEA)** projection.

See prjset() for a description of the API.

ceax2s()

```
int ceax2s (
              PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **cylindrical equal area (CEA)** projection.

ceax2s() deprojects Cartesian (x, y) coordinates in the plane of a **cylindrical equal area (CEA)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

ceas2x()

```
int ceas2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **cylindrical equal area (CEA)** projection.

ceas2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **cylindrical equal area (CEA)** projection.

See prjs2x() for a description of the API.

carset()

```
int carset (
             struct prjprm * prj )
```

Set up a prjprm struct for the **plate carrée (CAR)** projection.

carset() sets up a prjprm struct for a **plate carrée (CAR)** projection.

See prjset() for a description of the API.

carx2s()

```
int carx2s (
             PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **plate carrée (CAR)** projection.

carx2s() deprojects Cartesian (x, y) coordinates in the plane of a **plate carrée (CAR)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

cars2x()

```
int cars2x (
             PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **plate carrée (CAR)** projection.

cars2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **plate carrée (CAR)** projection.

See prjs2x() for a description of the API.

merset()

```
int merset (
             struct prjprm * prj )
```

Set up a prjprm struct for **Mercator's (MER)** projection.

merset() sets up a prjprm struct for a **Mercator (MER)** projection.

See prjset() for a description of the API.

merx2s()

```
int merx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for **Mercator's (MER)** projection.

merx2s() deprojects Cartesian (x, y) coordinates in the plane of a **Mercator (MER)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

mers2x()

```
int mers2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for **Mercator's (MER)** projection.

mers2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Mercator (MER)** projection.

See prjs2x() for a description of the API.

sflset()

```
int sflset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **Sanson-Flamsteed (SFL)** projection.

sflset() sets up a prjprm struct for a **Sanson-Flamsteed (SFL)** projection.

See prjset() for a description of the API.

sflx2s()

```
int sflx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **Sanson-Flamsteed (SFL)** projection.

sflx2s() deprojects Cartesian (x, y) coordinates in the plane of a **Sanson-Flamsteed (SFL)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

sfls2x()

```
int sfls2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **Sanson-Flamsteed (SFL)** projection.

sfls2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Sanson-Flamsteed (SFL)** projection.

See prjs2x() for a description of the API.

parset()

```
int parset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **parabolic (PAR)** projection.

parset() sets up a prjprm struct for a **parabolic (PAR)** projection.

See prjset() for a description of the API.

parx2s()

```
int parx2s (
              PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **parabolic (PAR)** projection.

parx2s() deprojects Cartesian (x, y) coordinates in the plane of a **parabolic (PAR)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

pars2x()

```
int pars2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **parabolic (PAR)** projection.

pars2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **parabolic (PAR)** projection.

See prjs2x() for a description of the API.

molset()

```
int molset (
            struct prjprm * prj )
```

Set up a prjprm struct for **Mollweide's (MOL)** projection.

molset() sets up a prjprm struct for a **Mollweide (MOL)** projection.

See prjset() for a description of the API.

molx2s()

```
int molx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for **Mollweide's (MOL)** projection.

molx2s() deprojects Cartesian (x, y) coordinates in the plane of a **Mollweide (MOL)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

mols2x()

```
int mols2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for **Mollweide's (MOL)** projection.

mols2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Mollweide (MOL)** projection.

See prjs2x() for a description of the API.

aitset()

```
int aitset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **Hammer-Aitoff (AIT)** projection.

aitset() sets up a prjprm struct for a **Hammer-Aitoff (AIT)** projection.

See prjset() for a description of the API.

aitx2s()

```
int aitx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **Hammer-Aitoff (AIT)** projection.

aitx2s() deprojects Cartesian (x, y) coordinates in the plane of a **Hammer-Aitoff (AIT)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

aits2x()

```
int aits2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **Hammer-Aitoff (AIT)** projection.

aits2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Hammer-Aitoff (AIT)** projection.

See prjs2x() for a description of the API.

copset()

```
int copset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **conic perspective (COP)** projection.

copset() sets up a prjprm struct for a **conic perspective (COP)** projection.

See prjset() for a description of the API.

copx2s()

```
int copx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **conic perspective (COP)** projection.

copx2s() deprojects Cartesian (x, y) coordinates in the plane of a **conic perspective (COP)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

cops2x()

```
int cops2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **conic perspective (COP)** projection.

cops2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **conic perspective (COP)** projection.

See prjs2x() for a description of the API.

coeset()

```
int coeset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **conic equal area (COE)** projection.

coeset() sets up a prjprm struct for a **conic equal area (COE)** projection.

See prjset() for a description of the API.

coex2s()

```
int coex2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **conic equal area (COE)** projection.

coex2s() deprojects Cartesian (x, y) coordinates in the plane of a **conic equal area (COE)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

coes2x()

```
int coes2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **conic equal area (COE)** projection.

coes2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **conic equal area (COE)** projection.

See prjs2x() for a description of the API.

codset()

```
int codset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **conic equidistant (COD)** projection.

codset() sets up a prjprm struct for a **conic equidistant (COD)** projection.

See prjset() for a description of the API.

codx2s()

```
int codx2s (
              PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **conic equidistant (COD)** projection.

codx2s() deprojects Cartesian (x, y) coordinates in the plane of a **conic equidistant (COD)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

cods2x()

```
int cods2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **conic equidistant (COD)** projection.

cods2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **conic equidistant (COD)** projection.

See prjs2x() for a description of the API.

cooset()

```
int cooset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **conic orthomorphic (COO)** projection.

cooset() sets up a prjprm struct for a **conic orthomorphic (COO)** projection.

See prjset() for a description of the API.

coox2s()

```
int coox2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **conic orthomorphic (COO)** projection.

coox2s() deprojects Cartesian (x, y) coordinates in the plane of a **conic orthomorphic (COO)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

coos2x()

```
int coos2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **conic orthomorphic (COO)** projection.

coos2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **conic orthomorphic (COO)** projection.

See prjs2x() for a description of the API.

bonset()

```
int bonset (
            struct prjprm * prj )
```

Set up a prjprm struct for **Bonne's (BON)** projection.

bonset() sets up a prjprm struct for a **Bonne (BON)** projection.

See prjset() for a description of the API.

bonx2s()

```
int bonx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for **Bonne's (BON)** projection.

bonx2s() deprojects Cartesian (x, y) coordinates in the plane of a **Bonne (BON)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

bons2x()

```
int bons2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for **Bonne's (BON)** projection.

bons2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Bonne (BON)** projection.

See prjs2x() for a description of the API.

pcoset()

```
int pcoset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **polyconic (PCO)** projection.

pcoset() sets up a prjprm struct for a **polyconic (PCO)** projection.

See prjset() for a description of the API.

pcox2s()

```
int pcox2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **polyconic (PCO)** projection.

pcox2s() deprojects Cartesian (x, y) coordinates in the plane of a **polyconic (PCO)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

pcos2x()

```
int pcos2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **polyconic (PCO)** projection.

pcos2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **polyconic (PCO)** projection.

See prjs2x() for a description of the API.

tscset()

```
int tscset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **tangential spherical cube (TSC)** projection.

tscset() sets up a prjprm struct for a **tangential spherical cube (TSC)** projection.

See prjset() for a description of the API.

tscx2s()

```
int tscx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **tangential spherical cube (TSC)** projection.

tscx2s() deprojects Cartesian (x, y) coordinates in the plane of a **tangential spherical cube (TSC)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

tscs2x()

```
int tscs2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **tangential spherical cube (TSC)** projection.

tscs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **tangential spherical cube (TSC)** projection.

See prjs2x() for a description of the API.

cscset()

```
int cscset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **COBE spherical cube (CSC)** projection.

cscset() sets up a prjprm struct for a **COBE spherical cube (CSC)** projection.

See prjset() for a description of the API.

cscx2s()

```
int cscx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **COBE spherical cube (CSC)** projection.

cscx2s() deprojects Cartesian (x, y) coordinates in the plane of a **COBE spherical cube (CSC)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

cscs2x()

```
int cscs2x (
            PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **COBE spherical cube (CSC)** projection.

cscs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **COBE spherical cube (CSC)** projection.

See prjs2x() for a description of the API.

qscset()

```
int qscset (
            struct prjprm * prj )
```

Set up a prjprm struct for the **quadrilateralized spherical cube (QSC)** projection.

qscset() sets up a prjprm struct for a **quadrilateralized spherical cube (QSC)** projection.

See prjset() for a description of the API.

qscx2s()

```
int qscx2s (
            PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **quadrilateralized spherical cube (QSC)** projection.

qscx2s() deprojects Cartesian (x, y) coordinates in the plane of a **quadrilateralized spherical cube (QSC)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

qscs2x()

```
int qscs2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **quadrilateralized spherical cube (QSC)** projection.

qscs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **quadrilateralized spherical cube (QSC)** projection.

See prjs2x() for a description of the API.

hpxset()

```
int hpxset (
              struct prjprm * prj )
```

Set up a prjprm struct for the **HEALPix (HPX)** projection.

hpxset() sets up a prjprm struct for a **HEALPix (HPX)** projection.

See prjset() for a description of the API.

hpxx2s()

```
int hpxx2s (
              PRJX2S_ARGS  )
```

Cartesian-to-spherical transformation for the **HEALPix (HPX)** projection.

hpxx2s() deprojects Cartesian (x, y) coordinates in the plane of a **HEALPix (HPX)** projection to native spherical coordinates (ϕ, θ).

See prjx2s() for a description of the API.

hpxs2x()

```
int hpxs2x (
              PRJS2X_ARGS  )
```

Spherical-to-Cartesian transformation for the **HEALPix (HPX)** projection.

hpxs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **HEALPix (HPX)** projection.

See prjs2x() for a description of the API.

xphset()

```
int xphset (
              struct prjprm * prj )
```

xphx2s()

```
int xphx2s (
              PRJX2S_ARGS  )
```

xphs2x()

```
int xphs2x (
              PRJS2X_ARGS  )
```

6.13.5 Variable Documentation

prj_errmsg

```
const char * prj_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

CONIC

```
const int CONIC  [extern]
```

Identifier for conic projections.

Identifier for conic projections, see prjprm::category.

CONVENTIONAL

```
const int CONVENTIONAL
```

Identifier for conventional projections.

Identifier for conventional projections, see prjprm::category.

CYLINDRICAL

```
const int CYLINDRICAL
```

Identifier for cylindrical projections.

Identifier for cylindrical projections, see prjprm::category.

POLYCONIC

```
const int POLYCONIC
```

Identifier for polyconic projections.

Identifier for polyconic projections, see prjprm::category.

PSEUDOCYLINDRICAL

```
const int PSEUDOCYLINDRICAL
```

Identifier for pseudocylindrical projections.

Identifier for pseudocylindrical projections, see prjprm::category.

QUADCUBE

```
const int QUADCUBE
```

Identifier for quadcube projections.

Identifier for quadcube projections, see prjprm::category.

ZENITHAL

```
const int ZENITHAL
```

Identifier for zenithal/azimuthal projections.

Identifier for zenithal/azimuthal projections, see prjprm::category.

HEALPIX

```
const int HEALPIX
```

Identifier for the HEALPix projection.

Identifier for the HEALPix projection, see prjprm::category.

prj_categories

```
const char prj_categories[9][32]  [extern]
```

Projection categories.

Names of the projection categories, all in lower-case except for "HEALPix".

Provided for information only, not used by the projection routines.

prj_ncode

```
const int prj_ncode  [extern]
```

The number of recognized three-letter projection codes.

The number of recognized three-letter projection codes (currently 27), see prj_codes.

prj_codes

```
const char prj_codes[27][4]  [extern]
```

Recognized three-letter projection codes.

List of all recognized three-letter projection codes (currently 27), e.g. **SIN**, **TAN**, etc.

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the prj routines
00031 * ---------------------------
00032 * Routines in this suite  implement the spherical map projections defined by
00033 * the FITS World Coordinate System (WCS) standard, as described in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 =
00038 =   "Representations of celestial coordinates in FITS",
00039 =   Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
00040 =
00041 =   "Mapping on the HEALPix grid",
00042 =   Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865 (WCS Paper V)
00043 =
00044 =   "Representing the 'Butterfly' Projection in FITS -- Projection Code XPH",
00045 =   Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050 (WCS Paper VI)
00046 *
00047 * These routines are based on the prjprm struct which contains all information
00048 * needed for the computations.  The struct contains some members that must be
00049 * set by the user, and others that are maintained by these routines, somewhat
00050 * like a C++ class but with no encapsulation.
00051 *
00052 * Routine prjini() is provided to initialize the prjprm struct with default
00053 * values, prjfree() reclaims any memory that may have been allocated to store
```

```
00054 * an error message, prjsize() computes its total size including allocated
00055 * memory, and prjprt() prints its contents.
00056 *
00057 * prjperr() prints the error message(s) (if any) stored in a prjprm struct.
00058 * prjbchk() performs bounds checking on native spherical coordinates.
00059 *
00060 * Setup routines for each projection with names of the form ???set(), where
00061 * "???" is the down-cased three-letter projection code, compute intermediate
00062 * values in the prjprm struct from parameters in it that were supplied by the
00063 * user.  The struct always needs to be set by the projection's setup routine
00064 * but that need not be called explicitly - refer to the explanation of
00065 * prjprm::flag.
00066 *
00067 * Each map projection is implemented via separate functions for the spherical
00068 * projection, ???s2x(), and deprojection, ???x2s().
00069 *
00070 * A set of driver routines, prjset(), prjx2s(), and prjs2x(), provides a
00071 * generic interface to the specific projection routines which they invoke
00072 * via pointers-to-functions stored in the prjprm struct.
00073 *
00074 * In summary, the routines are:
00075 *   - prjini()               Initialization routine for the prjprm struct.
00076 *   - prjfree()              Reclaim memory allocated for error messages.
00077 *   - prjsize()              Compute total size of a prjprm struct.
00078 *   - prjprt()               Print a prjprm struct.
00079 *   - prjperr()              Print error message (if any).
00080 *   - prjbchk()              Bounds checking on native coordinates.
00081 *
00082 *   - prjset(), prjx2s(), prjs2x():   Generic driver routines
00083 *
00084 *   - azpset(), azpx2s(), azps2x():   AZP (zenithal/azimuthal perspective)
00085 *   - szpset(), szpx2s(), szps2x():   SZP (slant zenithal perspective)
00086 *   - tanset(), tanx2s(), tans2x():   TAN (gnomonic)
00087 *   - stgset(), stgx2s(), stgs2x():   STG (stereographic)
00088 *   - sinset(), sinx2s(), sins2x():   SIN (orthographic/synthesis)
00089 *   - arcset(), arcx2s(), arcs2x():   ARC (zenithal/azimuthal equidistant)
00090 *   - zpnset(), zpnx2s(), zpns2x():   ZPN (zenithal/azimuthal polynomial)
00091 *   - zeaset(), zeax2s(), zeas2x():   ZEA (zenithal/azimuthal equal area)
00092 *   - airset(), airx2s(), airs2x():   AIR (Airy)
00093 *   - cypset(), cypx2s(), cyps2x():   CYP (cylindrical perspective)
00094 *   - ceaset(), ceax2s(), ceas2x():   CEA (cylindrical equal area)
00095 *   - carset(), carx2s(), cars2x():   CAR (Plate carree)
00096 *   - merset(), merx2s(), mers2x():   MER (Mercator)
00097 *   - sflset(), sflx2s(), sfls2x():   SFL (Sanson-Flamsteed)
00098 *   - parset(), parx2s(), pars2x():   PAR (parabolic)
00099 *   - molset(), molx2s(), mols2x():   MOL (Mollweide)
00100 *   - aitset(), aitx2s(), aits2x():   AIT (Hammer-Aitoff)
00101 *   - copset(), copx2s(), cops2x():   COP (conic perspective)
00102 *   - coeset(), coex2s(), coes2x():   COE (conic equal area)
00103 *   - codset(), codx2s(), cods2x():   COD (conic equidistant)
00104 *   - cooset(), coox2s(), coos2x():   COO (conic orthomorphic)
00105 *   - bonset(), bonx2s(), bons2x():   BON (Bonne)
00106 *   - pcoset(), pcox2s(), pcos2x():   PCO (polyconic)
00107 *   - tscset(), tscx2s(), tscs2x():   TSC (tangential spherical cube)
00108 *   - cscset(), cscx2s(), cscs2x():   CSC (COBE spherical cube)
00109 *   - qscset(), qscx2s(), qscs2x():   QSC (quadrilateralized spherical cube)
00110 *   - hpxset(), hpxx2s(), hpxs2x():   HPX (HEALPix)
00111 *   - xphset(), xphx2s(), xphs2x():   XPH (HEALPix polar, aka "butterfly")
00112 *
00113 * Argument checking (projection routines):
00114 * ----------------------------------------
00115 * The values of phi and theta (the native longitude and latitude) normally lie
00116 * in the range [-180,180] for phi, and [-90,90] for theta.  However, all
00117 * projection routines will accept any value of phi and will not normalize it.
00118 *
00119 * The projection routines do not explicitly check that theta lies within the
00120 * range [-90,90].  They do check for any value of theta that produces an
00121 * invalid argument to the projection equations (e.g. leading to division by
00122 * zero).  The projection routines for AZP, SZP, TAN, SIN, ZPN, and COP also
00123 * return error 2 if (phi,theta) corresponds to the overlapped (far) side of
00124 * the projection but also return the corresponding value of (x,y).  This
00125 * strict bounds checking may be relaxed at any time by setting
00126 * prjprm::bounds%2 to 0 (rather than 1); the projections need not be
00127 * reinitialized.
00128 *
00129 * Argument checking (deprojection routines):
00130 * ------------------------------------------
00131 * Error checking on the projected coordinates (x,y) is limited to that
00132 * required to ascertain whether a solution exists.  Where a solution does
00133 * exist, an optional check is made that the value of phi and theta obtained
00134 * lie within the ranges [-180,180] for phi, and [-90,90] for theta.  This
00135 * check, performed by prjbchk(), is enabled by default.  It may be disabled by
00136 * setting prjprm::bounds%4 to 0 (rather than 1); the projections need not be
00137 * reinitialized.
00138 *
00139 * Accuracy:
00140 * ---------
```

```
00141 * No warranty is given for the accuracy of these routines (refer to the
00142 * copyright notice); intending users must satisfy for themselves their
00143 * adequacy for the intended purpose.  However, closure to a precision of at
00144 * least 1E-10 degree of longitude and latitude has been verified for typical
00145 * projection parameters on the 1 degree graticule of native longitude and
00146 * latitude (to within 5 degrees of any latitude where the projection may
00147 * diverge).  Refer to the tprj1.c and tprj2.c test routines that accompany
00148 * this software.
00149 *
00150 *
00151 * prjini() - Default constructor for the prjprm struct
00152 * ----------------------------------------------------
00153 * prjini() sets all members of a prjprm struct to default values.  It should
00154 * be used to initialize every prjprm struct.
00155 *
00156 * PLEASE NOTE: If the prjprm struct has already been initialized, then before
00157 * reinitializing, it prjfree() should be used to free any memory that may have
00158 * been allocated to store an error message.  A memory leak may otherwise
00159 * result.
00160 *
00161 * Returned:
00162 *   prj       struct prjprm*
00163 *                       Projection parameters.
00164 *
00165 * Function return value:
00166 *             int       Status return value:
00167 *                         0: Success.
00168 *                         1: Null prjprm pointer passed.
00169 *
00170 *
00171 * prjfree() - Destructor for the prjprm struct
00172 * --------------------------------------------
00173 * prjfree() frees any memory that may have been allocated to store an error
00174 * message in the prjprm struct.
00175 *
00176 * Given:
00177 *   prj       struct prjprm*
00178 *                       Projection parameters.
00179 *
00180 * Function return value:
00181 *             int       Status return value:
00182 *                         0: Success.
00183 *                         1: Null prjprm pointer passed.
00184 *
00185 *
00186 * prjsize() - Compute the size of a prjprm struct
00187 * -----------------------------------------------
00188 * prjsize() computes the full size of a prjprm struct, including allocated
00189 * memory.
00190 *
00191 * Given:
00192 *   prj       const struct prjprm*
00193 *                       Projection parameters.
00194 *
00195 *                       If NULL, the base size of the struct and the allocated
00196 *                       size are both set to zero.
00197 *
00198 * Returned:
00199 *   sizes     int[2]    The first element is the base size of the struct as
00200 *                       returned by sizeof(struct prjprm).  The second element
00201 *                       is the total allocated size, in bytes.  This figure
00202 *                       includes memory allocated for the constituent struct,
00203 *                       prjprm::err.
00204 *
00205 *                       It is not an error for the struct not to have been set
00206 *                       up via prjset().
00207 *
00208 * Function return value:
00209 *             int       Status return value:
00210 *                         0: Success.
00211 *
00212 *
00213 * prjprt() - Print routine for the prjprm struct
00214 * ----------------------------------------------
00215 * prjprt() prints the contents of a prjprm struct using wcsprintf().  Mainly
00216 * intended for diagnostic purposes.
00217 *
00218 * Given:
00219 *   prj       const struct prjprm*
00220 *                       Projection parameters.
00221 *
00222 * Function return value:
00223 *             int       Status return value:
00224 *                         0: Success.
00225 *                         1: Null prjprm pointer passed.
00226 *
00227 *
```

```
00228 * prjperr() - Print error messages from a prjprm struct
00229 * ---------------------------------------------------
00230 * prjperr() prints the error message(s) (if any) stored in a prjprm struct.
00231 * If there are no errors then nothing is printed.  It uses wcserr_prt(), q.v.
00232 *
00233 * Given:
00234 *   prj       const struct prjprm*
00235 *                       Projection parameters.
00236 *
00237 *   prefix    const char *
00238 *                       If non-NULL, each output line will be prefixed with
00239 *                       this string.
00240 *
00241 * Function return value:
00242 *             int       Status return value:
00243 *                         0: Success.
00244 *                         1: Null prjprm pointer passed.
00245 *
00246 *
00247 * prjbchk() - Bounds checking on native coordinates
00248 * -------------------------------------------------
00249 * prjbchk() performs bounds checking on native spherical coordinates.  As
00250 * returned by the deprojection (x2s) routines, native longitude is expected
00251 * to lie in the closed interval [-180,180], with latitude in [-90,90].
00252 *
00253 * A tolerance may be specified to provide a small allowance for numerical
00254 * imprecision.  Values that lie outside the allowed range by not more than
00255 * the specified tolerance will be adjusted back into range.
00256 *
00257 * If prjprm::bounds&4 is set, as it is by prjini(), then prjbchk() will be
00258 * invoked automatically by the Cartesian-to-spherical deprojection (x2s)
00259 * routines with an appropriate tolerance set for each projection.
00260 *
00261 * Given:
00262 *   tol       double    Tolerance for the bounds check [deg].
00263 *
00264 *   nphi,
00265 *   ntheta    int       Vector lengths.
00266 *
00267 *   spt       int       Vector stride.
00268 *
00269 * Given and returned:
00270 *   phi,theta double[]  Native longitude and latitude (phi,theta) [deg].
00271 *
00272 * Returned:
00273 *   stat      int[]     Status value for each vector element:
00274 *                         0: Valid value of (phi,theta).
00275 *                         1: Invalid value.
00276 *
00277 * Function return value:
00278 *             int       Status return value:
00279 *                         0: Success.
00280 *                         1: One or more of the (phi,theta) coordinates
00281 *                            were, invalid, as indicated by the stat vector.
00282 *
00283 *
00284 * prjset() - Generic setup routine for the prjprm struct
00285 * ------------------------------------------------------
00286 * prjset() sets up a prjprm struct according to information supplied within
00287 * it.
00288 *
00289 * Note that this routine need not be called directly; it will be invoked by
00290 * prjx2s() and prjs2x() if prj.flag is anything other than a predefined magic
00291 * value.
00292 *
00293 * The one important distinction between prjset() and the setup routines for
00294 * the specific projections is that the projection code must be defined in the
00295 * prjprm struct in order for prjset() to identify the required projection.
00296 * Once prjset() has initialized the prjprm struct, prjx2s() and prjs2x() use
00297 * the pointers to the specific projection and deprojection routines contained
00298 * therein.
00299 *
00300 * Given and returned:
00301 *   prj       struct prjprm*
00302 *                       Projection parameters.
00303 *
00304 * Function return value:
00305 *             int       Status return value:
00306 *                         0: Success.
00307 *                         1: Null prjprm pointer passed.
00308 *                         2: Invalid projection parameters.
00309 *
00310 *                       For returns > 1, a detailed error message is set in
00311 *                       prjprm::err if enabled, see wcserr_enable().
00312 *
00313 *
00314 * prjx2s() - Generic Cartesian-to-spherical deprojection
```

```
00315 * ------------------------------------------------------
00316 * Deproject Cartesian (x,y) coordinates in the plane of projection to native
00317 * spherical coordinates (phi,theta).
00318 *
00319 * The projection is that specified by prjprm::code.
00320 *
00321 * Given and returned:
00322 *   prj       struct prjprm*
00323 *                       Projection parameters.
00324 *
00325 * Given:
00326 *   nx,ny     int       Vector lengths.
00327 *
00328 *   sxy,spt   int       Vector strides.
00329 *
00330 *   x,y       const double[]
00331 *                       Projected coordinates.
00332 *
00333 * Returned:
00334 *   phi,theta double[]  Longitude and latitude (phi,theta) of the projected
00335 *                       point in native spherical coordinates [deg].
00336 *
00337 *   stat      int[]     Status value for each vector element:
00338 *                         0: Success.
00339 *                         1: Invalid value of (x,y).
00340 *
00341 * Function return value:
00342 *             int       Status return value:
00343 *                         0: Success.
00344 *                         1: Null prjprm pointer passed.
00345 *                         2: Invalid projection parameters.
00346 *                         3: One or more of the (x,y) coordinates were
00347 *                            invalid, as indicated by the stat vector.
00348 *
00349 *                       For returns > 1, a detailed error message is set in
00350 *                       prjprm::err if enabled, see wcserr_enable().
00351 *
00352 *
00353 * prjs2x() - Generic spherical-to-Cartesian projection
00354 * ----------------------------------------------------
00355 * Project native spherical coordinates (phi,theta) to Cartesian (x,y)
00356 * coordinates in the plane of projection.
00357 *
00358 * The projection is that specified by prjprm::code.
00359 *
00360 * Given and returned:
00361 *   prj       struct prjprm*
00362 *                       Projection parameters.
00363 *
00364 * Given:
00365 *   nphi,
00366 *   ntheta    int       Vector lengths.
00367 *
00368 *   spt,sxy   int       Vector strides.
00369 *
00370 *   phi,theta const double[]
00371 *                       Longitude and latitude (phi,theta) of the projected
00372 *                       point in native spherical coordinates [deg].
00373 *
00374 * Returned:
00375 *   x,y       double[]  Projected coordinates.
00376 *
00377 *   stat      int[]     Status value for each vector element:
00378 *                         0: Success.
00379 *                         1: Invalid value of (phi,theta).
00380 *
00381 * Function return value:
00382 *             int       Status return value:
00383 *                         0: Success.
00384 *                         1: Null prjprm pointer passed.
00385 *                         2: Invalid projection parameters.
00386 *                         4: One or more of the (phi,theta) coordinates
00387 *                            were, invalid, as indicated by the stat vector.
00388 *
00389 *                       For returns > 1, a detailed error message is set in
00390 *                       prjprm::err if enabled, see wcserr_enable().
00391 *
00392 *
00393 * ???set() - Specific setup routines for the prjprm struct
00394 * --------------------------------------------------------
00395 * Set up a prjprm struct for a particular projection according to information
00396 * supplied within it.
00397 *
00398 * Given and returned:
00399 *   prj       struct prjprm*
00400 *                       Projection parameters.
00401 *
```

```
00402 * Function return value:
00403 *             int       Status return value:
00404 *                         0: Success.
00405 *                         1: Null prjprm pointer passed.
00406 *                         2: Invalid projection parameters.
00407 *
00408 *                       For returns > 1, a detailed error message is set in
00409 *                       prjprm::err if enabled, see wcserr_enable().
00410 *
00411 *
00412 * ???x2s() - Specific Cartesian-to-spherical deprojection routines
00413 * ----------------------------------------------------------------
00414 * Transform (x,y) coordinates in the plane of projection to native spherical
00415 * coordinates (phi,theta).
00416 *
00417 * Given and returned:
00418 *   prj       struct prjprm*
00419 *                       Projection parameters.
00420 *
00421 * Given:
00422 *   nx,ny     int       Vector lengths.
00423 *
00424 *   sxy,spt   int       Vector strides.
00425 *
00426 *   x,y       const double[]
00427 *                       Projected coordinates.
00428 *
00429 * Returned:
00430 *   phi,theta double[]  Longitude and latitude of the projected point in
00431 *                       native spherical coordinates [deg].
00432 *
00433 *   stat      int[]     Status value for each vector element:
00434 *                         0: Success.
00435 *                         1: Invalid value of (x,y).
00436 *
00437 * Function return value:
00438 *             int       Status return value:
00439 *                         0: Success.
00440 *                         1: Null prjprm pointer passed.
00441 *                         2: Invalid projection parameters.
00442 *                         3: One or more of the (x,y) coordinates were
00443 *                            invalid, as indicated by the stat vector.
00444 *
00445 *                       For returns > 1, a detailed error message is set in
00446 *                       prjprm::err if enabled, see wcserr_enable().
00447 *
00448 *
00449 * ???s2x() - Specific spherical-to-Cartesian projection routines
00450 *----------------------------------------------------------------
00451 * Transform native spherical coordinates (phi,theta) to (x,y) coordinates in
00452 * the plane of projection.
00453 *
00454 * Given and returned:
00455 *   prj       struct prjprm*
00456 *                       Projection parameters.
00457 *
00458 * Given:
00459 *   nphi,
00460 *   ntheta    int       Vector lengths.
00461 *
00462 *   spt,sxy   int       Vector strides.
00463 *
00464 *   phi,theta const double[]
00465 *                       Longitude and latitude of the projected point in
00466 *                       native spherical coordinates [deg].
00467 *
00468 * Returned:
00469 *   x,y       double[]  Projected coordinates.
00470 *
00471 *   stat      int[]     Status value for each vector element:
00472 *                         0: Success.
00473 *                         1: Invalid value of (phi,theta).
00474 *
00475 * Function return value:
00476 *             int       Status return value:
00477 *                         0: Success.
00478 *                         1: Null prjprm pointer passed.
00479 *                         2: Invalid projection parameters.
00480 *                         4: One or more of the (phi,theta) coordinates
00481 *                            were, invalid, as indicated by the stat vector.
00482 *
00483 *                       For returns > 1, a detailed error message is set in
00484 *                       prjprm::err if enabled, see wcserr_enable().
00485 *
00486 *
00487 * prjprm struct - Projection parameters
00488 * ------------------------------------
```

```
00489 * The prjprm struct contains all information needed to project or deproject
00490 * native spherical coordinates.  It consists of certain members that must be
00491 * set by the user ("given") and others that are set by the WCSLIB routines
00492 * ("returned").  Some of the latter are supplied for informational purposes
00493 * while others are for internal use only.
00494 *
00495 *   int flag
00496 *     (Given and returned) This flag must be set to zero whenever any of the
00497 *     following prjprm struct members are set or changed:
00498 *
00499 *       - prjprm::code,
00500 *       - prjprm::r0,
00501 *       - prjprm::pv[],
00502 *       - prjprm::phi0,
00503 *       - prjprm::theta0.
00504 *
00505 *     This signals the initialization routine (prjset() or ???set()) to
00506 *     recompute the returned members of the prjprm struct.  flag will then be
00507 *     reset to indicate that this has been done.
00508 *
00509 *     Note that flag need not be reset when prjprm::bounds is changed.
00510 *
00511 *   char code[4]
00512 *     (Given) Three-letter projection code defined by the FITS standard.
00513 *
00514 *   double r0
00515 *     (Given) The radius of the generating sphere for the projection, a linear
00516 *     scaling parameter.  If this is zero, it will be reset to its default
00517 *     value of 180/pi (the value for FITS WCS).
00518 *
00519 *   double pv[30]
00520 *     (Given) Projection parameters.  These correspond to the PVi_ma keywords
00521 *     in FITS, so pv[0] is PVi_0a, pv[1] is PVi_1a, etc., where i denotes the
00522 *     latitude-like axis.  Many projections use pv[1] (PVi_1a), some also use
00523 *     pv[2] (PVi_2a) and SZP uses pv[3] (PVi_3a).  ZPN is currently the only
00524 *     projection that uses any of the others.
00525 *
00526 *     Usage of the pv[] array as it applies to each projection is described in
00527 *     the prologue to each trio of projection routines in prj.c.
00528 *
00529 *   double phi0
00530 *     (Given) The native longitude, phi_0 [deg], and ...
00531 *   double theta0
00532 *     (Given) ... the native latitude, theta_0 [deg], of the reference point,
00533 *     i.e. the point (x,y) = (0,0).  If undefined (set to a magic value by
00534 *     prjini()) the initialization routine will set this to a
00535 *     projection-specific default.
00536 *
00537 *   int bounds
00538 *     (Given) Controls bounds checking.  If bounds&1 then enable strict bounds
00539 *     checking for the spherical-to-Cartesian (s2x) transformation for the
00540 *     AZP, SZP, TAN, SIN, ZPN, and COP projections.  If bounds&2 then enable
00541 *     strict bounds checking for the Cartesian-to-spherical transformation
00542 *     (x2s) for the HPX and XPH projections.  If bounds&4 then the Cartesian-
00543 *     to-spherical transformations (x2s) will invoke prjbchk() to perform
00544 *     bounds checking on the computed native coordinates, with a tolerance set
00545 *     to suit each projection.  bounds is set to 7 by prjini() by default
00546 *     which enables all checks.  Zero it to disable all checking.
00547 *
00548 *     It is not necessary to reset the prjprm struct (via prjset() or
00549 *     ???set()) when prjprm::bounds is changed.
00550 *
00551 * The remaining members of the prjprm struct are maintained by the setup
00552 * routines and must not be modified elsewhere:
00553 *
00554 *   char name[40]
00555 *     (Returned) Long name of the projection.
00556 *
00557 *     Provided for information only, not used by the projection routines.
00558 *
00559 *   int  category
00560 *     (Returned) Projection category matching the value of the relevant global
00561 *     variable:
00562 *
00563 *     - ZENITHAL,
00564 *     - CYLINDRICAL,
00565 *     - PSEUDOCYLINDRICAL,
00566 *     - CONVENTIONAL,
00567 *     - CONIC,
00568 *     - POLYCONIC,
00569 *     - QUADCUBE, and
00570 *     - HEALPIX.
00571 *
00572 *     The category name may be identified via the prj_categories character
00573 *     array, e.g.
00574 *
00575 =       struct prjprm prj;
```

```
00576 =         ...
00577 =       printf("%s\n", prj_categories[prj.category]);
00578 *
00579 *     Provided for information only, not used by the projection routines.
00580 *
00581 *   int  pvrange
00582 *     (Returned) Range of projection parameter indices: 100 times the first
00583 *     allowed index plus the number of parameters, e.g. TAN is 0 (no
00584 *     parameters), SZP is 103 (1 to 3), and ZPN is 30 (0 to 29).
00585 *
00586 *     Provided for information only, not used by the projection routines.
00587 *
00588 *   int  simplezen
00589 *     (Returned) True if the projection is a radially-symmetric zenithal
00590 *     projection.
00591 *
00592 *     Provided for information only, not used by the projection routines.
00593 *
00594 *   int  equiareal
00595 *     (Returned) True if the projection is equal area.
00596 *
00597 *     Provided for information only, not used by the projection routines.
00598 *
00599 *   int  conformal
00600 *     (Returned) True if the projection is conformal.
00601 *
00602 *     Provided for information only, not used by the projection routines.
00603 *
00604 *   int  global
00605 *     (Returned) True if the projection can represent the whole sphere in a
00606 *     finite, non-overlapped mapping.
00607 *
00608 *     Provided for information only, not used by the projection routines.
00609 *
00610 *   int  divergent
00611 *     (Returned) True if the projection diverges in latitude.
00612 *
00613 *     Provided for information only, not used by the projection routines.
00614 *
00615 *   double x0
00616 *     (Returned) The offset in x, and ...
00617 *   double y0
00618 *     (Returned) ... the offset in y used to force (x,y) = (0,0) at
00619 *     (phi_0,theta_0).
00620 *
00621 *   struct wcserr *err
00622 *     (Returned) If enabled, when an error status is returned, this struct
00623 *     contains detailed information about the error, see wcserr_enable().
00624 *
00625 *   void *padding
00626 *     (An unused variable inserted for alignment purposes only.)
00627 *
00628 *   double w[10]
00629 *     (Returned) Intermediate floating-point values derived from the
00630 *     projection parameters, cached here to save recomputation.
00631 *
00632 *     Usage of the w[] array as it applies to each projection is described in
00633 *     the prologue to each trio of projection routines in prj.c.
00634 *
00635 *   int n
00636 *     (Returned) Intermediate integer value (used only for the ZPN and HPX
00637 *     projections).
00638 *
00639 *   int (*prjx2s)(PRJX2S_ARGS)
00640 *     (Returned) Pointer to the spherical projection ...
00641 *   int (*prjs2x)(PRJ_ARGS)
00642 *     (Returned) ... and deprojection routines.
00643 *
00644 *
00645 * Global variable: const char *prj_errmsg[] - Status return messages
00646 * ---------------------------------------------------------------------
00647 * Error messages to match the status value returned from each function.
00648 *
00649 *===========================================================================*/

6.15.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with spectral coordinates, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)
```

These routines define methods to be used for computing spectral world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa. They are based on the spcprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Routine spcini() is provided to initialize the spcprm struct with default values, spcfree() reclaims any memory that may have been allocated to store an error message, spcsize() computes its total size including allocated memory, and spcprt() prints its contents.

spcperr() prints the error message(s) (if any) stored in a spcprm struct.

A setup routine, spcset(), computes intermediate values in the spcprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by spcset() but it need not be called explicitly - refer to the explanation of spcprm::flag.

spcx2s() and spcs2x() implement the WCS spectral coordinate transformations. In fact, they are high level driver routines for the lower level spectral coordinate transformation routines described in spx.h.

A number of routines are provided to aid in analysing or synthesising sets of FITS spectral axis keywords:

- spctype() checks a spectral **CTYPE**`ia` keyword for validity and returns information derived from it.
- Spectral keyword analysis routine spcspxe() computes the values of the X-type spectral variables for the S-type variables supplied.
- Spectral keyword synthesis routine, spcxpse(), computes the S-type variables for the X-types supplied.
- Given a set of spectral keywords, a translation routine, spctrne(), produces the corresponding set for the specified spectral **CTYPE**`ia`.
- spcaips() translates AIPS-convention spectral **CTYPE**`ia` and **VELREF** keyvalues.

Spectral variable types - S, P, and X:
A few words of explanation are necessary regarding spectral variable types in FITS.

Every FITS spectral axis has three associated spectral variables:

S-type: the spectral variable in which coordinates are to be expressed. Each S-type is encoded as four characters and is linearly related to one of four basic types as follows:

F (Frequency):

- '**FREQ**': frequency
- '**AFRQ**': angular frequency
- '**ENER**': photon energy
- '**WAVN**': wave number

- '**VRAD**': radio velocity

W (Wavelength in vacuo):

- '**WAVE**': wavelength
- '**VOPT**': optical velocity
- '**ZOPT**': redshift

A (wavelength in Air):

- '**AWAV**': wavelength in air

V (Velocity):

- '**VELO**': relativistic velocity
- '**BETA**': relativistic beta factor

The S-type forms the first four characters of the **CTYPE**ia keyvalue, and **CRVAL**ia and **CDELT**ia are expressed as S-type quantities so that they provide a first-order approximation to the S-type variable at the reference point.

Note that '**AFRQ**', angular frequency, is additional to the variables defined in WCS Paper III.

P-type: the basic spectral variable (F, W, A, or V) with which the S-type variable is associated (see list above).

For non-grism axes, the P-type is encoded as the eighth character of **CTYPE**ia.

X-type: the basic spectral variable (F, W, A, or V) for which the spectral axis is linear, grisms excluded (see below).

For non-grism axes, the X-type is encoded as the sixth character of **CTYPE**ia.

Grisms: Grism axes have normal S-, and P-types but the axis is linear, not in any spectral variable, but in a special "grism parameter". The X-type spectral variable is either W or A for grisms in vacuo or air respectively, but is encoded as 'w' or 'a' to indicate that an additional transformation is required to convert to or from the grism parameter. The spectral algorithm code for grisms also has a special encoding in **CTYPE**ia, either '**GRI**' (in vacuo) or '**GRA**' (in air).

In the algorithm chain, the non-linear transformation occurs between the X-type and the P-type variables; the transformation between P-type and S-type variables is always linear.

When the P-type and X-type variables are the same, the spectral axis is linear in the S-type variable and the second four characters of **CTYPE**ia are blank. This can never happen for grism axes.

As an example, correlating radio spectrometers always produce spectra that are regularly gridded in frequency; a redshift scale on such a spectrum is non-linear. The required value of **CTYPE**ia would be **'ZOPT-F2W'**, where the desired S-type is '**ZOPT**' (redshift), the P-type is necessarily 'W' (wavelength), and the X-type is 'F' (frequency) by the nature of the instrument.

Air-to-vacuum wavelength conversion:
Please refer to the prologue of spx.h for important comments relating to the air-to-vacuum wavelength conversion.

Argument checking:
The input spectral values are only checked for values that would result in floating point exceptions. In particular, negative frequencies and wavelengths are allowed, as are velocities greater than the speed of light. The same is true for the spectral parameters - rest frequency and wavelength.

Accuracy:
No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine tspc.c which accompanies this software.

6.15.2 Macro Definition Documentation

SPCLEN

```
#define SPCLEN (sizeof(struct spcprm)/sizeof(int))
```

Size of the spcprm struct in *int* units.

Size of the spcprm struct in *int* units, used by the Fortran wrappers.

spcini_errmsg

SPCERR_BAD_SPEC	

6.15.4 Function Documentation

spcini()

```
int spcini (
             struct spcprm * spc )
```

Default constructor for the spcprm struct.

spcini() sets all members of a spcprm struct to default values. It should be used to initialize every spcprm struct.

PLEASE NOTE: If the spcprm struct has already been initialized, then before reinitializing, it spcfree() should be used to free any memory that may have been allocated to store an error message. A memory leak may otherwise result.

Parameters

in,out	*spc*	Spectral transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcfree()

```
int spcfree (
             struct spcprm * spc )
```

Destructor for the spcprm struct.

spcfree() frees any memory that may have been allocated to store an error message in the spcprm struct.

Parameters

in	*spc*	Spectral transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcsize()

```
int spcsize (
            const struct spcprm * spc,
            int sizes[2] )
```

Compute the size of a spcprm struct.

spcsize() computes the full size of a spcprm struct, including allocated memory.

Parameters

in	*spc*	Spectral transformation parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct spcprm). The second element is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct, spcprm::err. It is not an error for the struct not to have been set up via spcset().

Returns

Status return value:

- 0: Success.

spcprt()

```
int spcprt (
            const struct spcprm * spc )
```

Print routine for the spcprm struct.

spcprt() prints the contents of a spcprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*spc*	Spectral transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcperr()

```
int spcperr (
            const struct spcprm * spc,
            const char * prefix )
```

Print error messages from a spcprm struct.

spcperr() prints the error message(s) (if any) stored in a spcprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*spc*	Spectral transformation parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcset()

```
int spcset (
            struct spcprm * spc )
```

Setup routine for the spcprm struct.

spcset() sets up a spcprm struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by spcx2s() and spcs2x() if spcprm::flag is anything other than a predefined magic value.

Parameters

in,out	*spc*	Spectral transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.
- 2: Invalid spectral parameters.

For returns $>$ 1, a detailed error message is set in spcprm::err if enabled, see wcserr_enable().

spcx2s()

```
int spcx2s (
              struct spcprm * spc,
              int nx,
              int sx,
              int sspec,
              const double x[],
              double spec[],
              int stat[] )
```

Transform to spectral coordinates.

spcx2s() transforms intermediate world coordinates to spectral coordinates.

Parameters

in,out	*spc*	Spectral transformation parameters.
in	*nx*	Vector length.
in	*sx*	Vector stride.
in	*sspec*	Vector stride.
in	*x*	Intermediate world coordinates, in SI units.
out	*spec*	Spectral coordinates, in SI units.
out	*stat*	Status return value status for each vector element: • 0: Success. • 1: Invalid value of x.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.
- 2: Invalid spectral parameters.
- 3: One or more of the x coordinates were invalid, as indicated by the stat vector.

For returns $>$ 1, a detailed error message is set in spcprm::err if enabled, see wcserr_enable().

spcs2x()

```
int spcs2x (
              struct spcprm * spc,
              int nspec,
              int sspec,
              int sx,
              const double spec[],
              double x[],
              int stat[] )
```

Transform spectral coordinates.

spcs2x() transforms spectral world coordinates to intermediate world coordinates.

Parameters

in,out	*spc*	Spectral transformation parameters.
in	*nspec*	Vector length.
in	*sspec*	Vector stride.
in	*sx*	Vector stride.
in	*spec*	Spectral coordinates, in SI units.
out	*x*	Intermediate world coordinates, in SI units.
out	*stat*	Status return value status for each vector element: • 0: Success. • 1: Invalid value of spec.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.
- 2: Invalid spectral parameters.
- 4: One or more of the spec coordinates were invalid, as indicated by the stat vector.

For returns $>$ 1, a detailed error message is set in spcprm::err if enabled, see wcserr_enable().

spctype()

```
int spctype (
             const char ctype[9],
             char stype[],
             char scode[],
             char sname[],
             char units[],
             char * ptype,
             char * xtype,
             int * restreq,
             struct wcserr ** err )
```

Spectral **CTYPE**ia keyword analysis.

spctype() checks whether a **CTYPE**ia keyvalue is a valid spectral axis type and if so returns information derived from it relating to the associated S-, P-, and X-type spectral variables (see explanation above).

The return arguments are guaranteed not be modified if **CTYPE**ia is not a valid spectral type; zero-pointers may be specified for any that are not of interest.

A deprecated form of this function, spctyp(), lacks the wcserr$**$ parameter.

Parameters

in	*ctype*	The **CTYPE**ia keyvalue, (eight characters with null termination).

Parameters

out	*stype*	The four-letter name of the S-type spectral variable copied or translated from ctype. If a non-zero pointer is given, the array must accomodate a null- terminated string of length 5.
out	*scode*	The three-letter spectral algorithm code copied or translated from ctype. Logarithmic ('**LOG**') and tabular ('**TAB**') codes are also recognized. If a non-zero pointer is given, the array must accomodate a null-terminated string of length 4.
out	*sname*	Descriptive name of the S-type spectral variable. If a non-zero pointer is given, the array must accomodate a null-terminated string of length 22.
out	*units*	SI units of the S-type spectral variable. If a non-zero pointer is given, the array must accomodate a null-terminated string of length 8.
out	*ptype*	Character code for the P-type spectral variable derived from ctype, one of 'F', 'W', 'A', or 'V'.
out	*xtype*	Character code for the X-type spectral variable derived from ctype, one of 'F', 'W', 'A', or 'V'. Also, 'w' and 'a' are synonymous to 'W' and 'A' for grisms in vacuo and air respectively. Set to 'L' or 'T' for logarithmic ('**LOG**') and tabular ('**TAB**') axes.
out	*restreq*	Multivalued flag that indicates whether rest frequency or wavelength is required to compute spectral variables for this **CTYPE**ia: • 0: Not required. • 1: Required for the conversion between S- and P-types (e.g. **'ZOPT-F2W'**). • 2: Required for the conversion between P- and X-types (e.g. **'BETA-W2V'**). • 3: Required for the conversion between S- and P-types, and between P- and X-types, but not between S- and X-types (this applies only for **'VRAD-V2F'**, **'VOPT-V2W'**, and **'ZOPT-V2W'**). Thus the rest frequency or wavelength is required for spectral coordinate computations (i.e. between S- and X-types) only if `restreq%3 != 0` .
out	*err*	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters (not a spectral **CTYPE**ia).

spcspxe()

```
int spcspxe (
            const char ctypeS[9],
            double crvalS,
            double restfrq,
            double restwav,
            char * ptype,
            char * xtype,
            int * restreq,
            double * crvalX,
```

```
            double * dXdS,
            struct wcserr ** err )
```

Spectral keyword analysis.

spcspxe() analyses the **CTYPE**ia and **CRVAL**ia FITS spectral axis keyword values and returns information about the associated X-type spectral variable.

A deprecated form of this function, spcspx(), lacks the wcserr$**$ parameter.

Parameters

in	*ctypeS*	Spectral axis type, i.e. the **CTYPE**ia keyvalue, (eight characters with null termination). For non-grism axes, the character code for the P-type spectral variable in the algorithm code (i.e. the eighth character of **CTYPE**ia) may be set to '?' (it will not be reset).
in	*crvalS*	Value of the S-type spectral variable at the reference point, i.e. the **CRVAL**ia keyvalue, SI units.
in	*restfrq,restwav*	Rest frequency [Hz] and rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero.
out	*ptype*	Character code for the P-type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
out	*xtype*	Character code for the X-type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'. Also, 'w' and 'a' are synonymous to 'W' and 'A' for grisms in vacuo and air respectively; crvalX and dXdS (see below) will conform to these.
out	*restreq*	Multivalued flag that indicates whether rest frequency or wavelength is required to compute spectral variables for this **CTYPE**ia, as for spctype().
out	*crvalX*	Value of the X-type spectral variable at the reference point, SI units.
out	*dXdS*	The derivative, dX/dS, evaluated at the reference point, SI units. Multiply the **CDELT**ia keyvalue by this to get the pixel spacing in the X-type spectral coordinate.
out	*err*	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.

spcxpse()

```
int spcxpse (
            const char ctypeS[9],
            double crvalX,
            double restfrq,
            double restwav,
            char * ptype,
            char * xtype,
            int * restreq,
```

```
            double * crvalS,
            double * dSdX,
            struct wcserr ** err )
```

Spectral keyword synthesis.

spcxpse(), for the spectral axis type specified and the value provided for the X-type spectral variable at the reference point, deduces the value of the FITS spectral axis keyword **CRVAL**ia and also the derivative dS/dX which may be used to compute **CDELT**ia. See above for an explanation of the S-, P-, and X-type spectral variables.

A deprecated form of this function, spcxps(), lacks the wcserr$**$ parameter.

Parameters

in	*ctypeS*	The required spectral axis type, i.e. the **CTYPE**ia keyvalue, (eight characters with null termination). For non-grism axes, the character code for the P-type spectral variable in the algorithm code (i.e. the eighth character of **CTYPE**ia) may be set to '?' (it will not be reset).
in	*crvalX*	Value of the X-type spectral variable at the reference point (N.B. NOT the **CRVAL**ia keyvalue), SI units.
in	*restfrq,restwav*	Rest frequency [Hz] and rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero.
out	*ptype*	Character code for the P-type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
out	*xtype*	Character code for the X-type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'. Also, 'w' and 'a' are synonymous to 'W' and 'A' for grisms; crvalX and cdeltX must conform to these.
out	*restreq*	Multivalued flag that indicates whether rest frequency or wavelength is required to compute spectral variables for this **CTYPE**ia, as for spctype().
out	*crvalS*	Value of the S-type spectral variable at the reference point (i.e. the appropriate **CRVAL**ia keyvalue), SI units.
out	*dSdX*	The derivative, dS/dX, evaluated at the reference point, SI units. Multiply this by the pixel spacing in the X-type spectral coordinate to get the **CDELT**ia keyvalue.
out	*err*	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.

spctrne()

```
int spctrne (
            const char ctypeS1[9],
            double crvalS1,
            double cdeltS1,
            double restfrq,
            double restwav,
```

```
char ctypeS2[9],
double * crvalS2,
double * cdeltS2,
struct wcserr ** err )
```

Spectral keyword translation.

spctrne() translates a set of FITS spectral axis keywords into the corresponding set for the specified spectral axis type. For example, a '**FREQ**' axis may be translated into **'ZOPT-F2W'** and vice versa.

A deprecated form of this function, spctrn(), lacks the wcserr** parameter.

Parameters

in	*ctypeS1*	Spectral axis type, i.e. the **CTYPE**ia keyvalue, (eight characters with null termination). For non-grism axes, the character code for the P-type spectral variable in the algorithm code (i.e. the eighth character of **CTYPE**ia) may be set to '?' (it will not be reset).
in	*crvalS1*	Value of the S-type spectral variable at the reference point, i.e. the **CRVAL**ia keyvalue, SI units.
in	*cdeltS1*	Increment of the S-type spectral variable at the reference point, SI units.
in	*restfrq,restwav*	Rest frequency [Hz] and rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero. Neither are required if the translation is between wave-characteristic types, or between velocity-characteristic types. E.g., required for '**FREQ**' -> **'ZOPT-F2W'**, but not required for **'VELO-F2V'** -> **'ZOPT-F2W'**.
in,out	*ctypeS2*	Required spectral axis type (eight characters with null termination). The first four characters are required to be given and are never modified. The remaining four, the algorithm code, are completely determined by, and must be consistent with, ctypeS1 and the first four characters of ctypeS2. A non-zero status value will be returned if they are inconsistent (see below). However, if the final three characters are specified as "???", or if just the eighth character is specified as '?', the correct algorithm code will be substituted (applies for grism axes as well as non-grism).
out	*crvalS2*	Value of the new S-type spectral variable at the reference point, i.e. the new **CRVAL**ia keyvalue, SI units.
out	*cdeltS2*	Increment of the new S-type spectral variable at the reference point, i.e. the new **CDELT**ia keyvalue, SI units.
out	*err*	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.

A status value of 2 will be returned if restfrq or restwav are not specified when required, or if ctypeS1 or ctypeS2 are self-inconsistent, or have different spectral X-type variables.

spcaips()

```
int spcaips (
             const char ctypeA[9],
             int velref,
             char ctype[9],
             char specsys[9] )
```

Translate AIPS-convention spectral keywords.

spcaips() translates AIPS-convention spectral **CTYPE**ia and **VELREF** keyvalues.

Parameters

in	*ctypeA*	**CTYPE**ia keyvalue possibly containing an AIPS-convention spectral code (eight characters, need not be null-terminated).
in	*velref*	AIPS-convention **VELREF** code. It has the following integer values: • 1: LSR kinematic, originally described simply as "LSR" without distinction between the kinematic and dynamic definitions. • 2: Barycentric, originally described as "HEL" meaning heliocentric. • 3: Topocentric, originally described as "OBS" meaning geocentric but widely interpreted as topocentric. AIPS++ extensions to **VELREF** are also recognized: • 4: LSR dynamic. • 5: Geocentric. • 6: Source rest frame. • 7: Galactocentric. For an AIPS '**VELO**' axis, a radio convention velocity (VRAD) is denoted by adding 256 to **VELREF**, otherwise an optical velocity (VOPT) is indicated (this is not applicable to '**FREQ**' or '**FELO**' axes). Setting velref to 0 or 256 chooses between optical and radio velocity without specifying a Doppler frame, provided that a frame is encoded in ctypeA. If not, i.e. for ctypeA = '**VELO**', ctype will be returned as '**VELO**'. **VELREF** takes precedence over **CTYPE**ia in defining the Doppler frame, e.g. `ctypeA = 'VELO-HEL'  velref = 1` returns ctype = '**VOPT**' with specsys set to 'LSRK'. If omitted from the header, the default value of **VELREF** is 0.
out	*ctype*	Translated **CTYPE**ia keyvalue, or a copy of ctypeA if no translation was performed (in which case any trailing blanks in ctypeA will be replaced with nulls).
out	*specsys*	Doppler reference frame indicated by **VELREF** or else by **CTYPE**ia with value corresponding to the SPECSYS keyvalue in the FITS WCS standard. May be returned blank if neither specifies a Doppler frame, e.g. ctypeA = '**FELO**' and velref%256 == 0.

Returns

Status return value:

- -1: No translation required (not an error).
- 0: Success.
- 2: Invalid value of **VELREF**.

spctyp()

```
int spctyp (
             const char ctype[9],
             char stype[],
             char scode[],
             char sname[],
             char units[],
             char * ptype,
             char * xtype,
             int * restreq )
```

spcspx()

```
int spcspx (
             const char ctypeS[9],
             double crvalS,
             double restfrq,
             double restwav,
             char * ptype,
             char * xtype,
             int * restreq,
             double * crvalX,
             double * dXdS )
```

spcxps()

```
int spcxps (
             const char ctypeS[9],
             double crvalX,
             double restfrq,
             double restwav,
             char * ptype,
             char * xtype,
             int * restreq,
             double * crvalS,
             double * dSdX )
```

spctrn()

```
int spctrn (
             const char ctypeS1[9],
             double crvalS1,
             double cdeltS1,
             double restfrq,
             double restwav,
             char ctypeS2[9],
             double * crvalS2,
             double * cdeltS2 )
```

6.15.5 Variable Documentation

spc_errmsg

```
const char * spc_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the spc routines
00031 * ---------------------------
00032 * Routines in this suite implement the part of the FITS World Coordinate
00033 * System (WCS) standard that deals with spectral coordinates, as described in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 =
00038 =   "Representations of spectral coordinates in FITS",
00039 =   Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00040 =   2006, A&A, 446, 747 (WCS Paper III)
00041 *
00042 * These routines define methods to be used for computing spectral world
00043 * coordinates from intermediate world coordinates (a linear transformation
00044 * of image pixel coordinates), and vice versa.  They are based on the spcprm
00045 * struct which contains all information needed for the computations.  The
00046 * struct contains some members that must be set by the user, and others that
00047 * are maintained by these routines, somewhat like a C++ class but with no
00048 * encapsulation.
00049 *
00050 * Routine spcini() is provided to initialize the spcprm struct with default
00051 * values, spcfree() reclaims any memory that may have been allocated to store
00052 * an error message, spcsize() computes its total size including allocated
00053 * memory, and spcprt() prints its contents.
00054 *
00055 * spcperr() prints the error message(s) (if any) stored in a spcprm struct.
00056 *
00057 * A setup routine, spcset(), computes intermediate values in the spcprm struct
00058 * from parameters in it that were supplied by the user.  The struct always
00059 * needs to be set up by spcset() but it need not be called explicitly - refer
00060 * to the explanation of spcprm::flag.
00061 *
00062 * spcx2s() and spcs2x() implement the WCS spectral coordinate transformations.
00063 * In fact, they are high level driver routines for the lower level spectral
00064 * coordinate transformation routines described in spx.h.
```

```
00065 *
00066 * A number of routines are provided to aid in analysing or synthesising sets
00067 * of FITS spectral axis keywords:
00068 *
00069 *   - spctype() checks a spectral CTYPEia keyword for validity and returns
00070 *     information derived from it.
00071 *
00072 *   - Spectral keyword analysis routine spcspxe() computes the values of the
00073 *     X-type spectral variables for the S-type variables supplied.
00074 *
00075 *   - Spectral keyword synthesis routine, spcxpse(), computes the S-type
00076 *     variables for the X-types supplied.
00077 *
00078 *   - Given a set of spectral keywords, a translation routine, spctrne(),
00079 *     produces the corresponding set for the specified spectral CTYPEia.
00080 *
00081 *   - spcaips() translates AIPS-convention spectral CTYPEia and VELREF
00082 *     keyvalues.
00083 *
00084 * Spectral variable types - S, P, and X:
00085 * --------------------------------------
00086 * A few words of explanation are necessary regarding spectral variable types
00087 * in FITS.
00088 *
00089 * Every FITS spectral axis has three associated spectral variables:
00090 *
00091 *   S-type: the spectral variable in which coordinates are to be
00092 *     expressed.  Each S-type is encoded as four characters and is
00093 *     linearly related to one of four basic types as follows:
00094 *
00095 *     F (Frequency):
00096 *       - 'FREQ':  frequency
00097 *       - 'AFRQ':  angular frequency
00098 *       - 'ENER':  photon energy
00099 *       - 'WAVN':  wave number
00100 *       - 'VRAD':  radio velocity
00101 *
00102 *     W (Wavelength in vacuo):
00103 *       - 'WAVE':  wavelength
00104 *       - 'VOPT':  optical velocity
00105 *       - 'ZOPT':  redshift
00106 *
00107 *     A (wavelength in Air):
00108 *       - 'AWAV':  wavelength in air
00109 *
00110 *     V (Velocity):
00111 *       - 'VELO':  relativistic velocity
00112 *       - 'BETA':  relativistic beta factor
00113 *
00114 *     The S-type forms the first four characters of the CTYPEia keyvalue,
00115 *     and CRVALia and CDELTia are expressed as S-type quantities so that
00116 *     they provide a first-order approximation to the S-type variable at
00117 *     the reference point.
00118 *
00119 *     Note that 'AFRQ', angular frequency, is additional to the variables
00120 *     defined in WCS Paper III.
00121 *
00122 *   P-type: the basic spectral variable (F, W, A, or V) with which the
00123 *     S-type variable is associated (see list above).
00124 *
00125 *     For non-grism axes, the P-type is encoded as the eighth character of
00126 *     CTYPEia.
00127 *
00128 *   X-type: the basic spectral variable (F, W, A, or V) for which the
00129 *     spectral axis is linear, grisms excluded (see below).
00130 *
00131 *     For non-grism axes, the X-type is encoded as the sixth character of
00132 *     CTYPEia.
00133 *
00134 *   Grisms: Grism axes have normal S-, and P-types but the axis is linear,
00135 *     not in any spectral variable, but in a special "grism parameter".
00136 *     The X-type spectral variable is either W or A for grisms in vacuo or
00137 *     air respectively, but is encoded as 'w' or 'a' to indicate that an
00138 *     additional transformation is required to convert to or from the
00139 *     grism parameter.  The spectral algorithm code for grisms also has a
00140 *     special encoding in CTYPEia, either 'GRI' (in vacuo) or 'GRA' (in air).
00141 *
00142 * In the algorithm chain, the non-linear transformation occurs between the
00143 * X-type and the P-type variables; the transformation between P-type and
00144 * S-type variables is always linear.
00145 *
00146 * When the P-type and X-type variables are the same, the spectral axis is
00147 * linear in the S-type variable and the second four characters of CTYPEia
00148 * are blank.  This can never happen for grism axes.
00149 *
00150 * As an example, correlating radio spectrometers always produce spectra that
00151 * are regularly gridded in frequency; a redshift scale on such a spectrum is
```

```
00152 * non-linear.  The required value of CTYPEia would be 'ZOPT-F2W', where the
00153 * desired S-type is 'ZOPT' (redshift), the P-type is necessarily 'W'
00154 * (wavelength), and the X-type is 'F' (frequency) by the nature of the
00155 * instrument.
00156 *
00157 * Air-to-vacuum wavelength conversion:
00158 * ------------------------------------
00159 * Please refer to the prologue of spx.h for important comments relating to the
00160 * air-to-vacuum wavelength conversion.
00161 *
00162 * Argument checking:
00163 * ------------------
00164 * The input spectral values are only checked for values that would result in
00165 * floating point exceptions.  In particular, negative frequencies and
00166 * wavelengths are allowed, as are velocities greater than the speed of
00167 * light.  The same is true for the spectral parameters - rest frequency and
00168 * wavelength.
00169 *
00170 * Accuracy:
00171 * ---------
00172 * No warranty is given for the accuracy of these routines (refer to the
00173 * copyright notice); intending users must satisfy for themselves their
00174 * adequacy for the intended purpose.  However, closure effectively to within
00175 * double precision rounding error was demonstrated by test routine tspc.c
00176 * which accompanies this software.
00177 *
00178 *
00179 * spcini() - Default constructor for the spcprm struct
00180 * ----------------------------------------------------
00181 * spcini() sets all members of a spcprm struct to default values.  It should
00182 * be used to initialize every spcprm struct.
00183 *
00184 * PLEASE NOTE: If the spcprm struct has already been initialized, then before
00185 * reinitializing, it spcfree() should be used to free any memory that may have
00186 * been allocated to store an error message.  A memory leak may otherwise
00187 * result.
00188 *
00189 * Given and returned:
00190 *   spc       struct spcprm*
00191 *                       Spectral transformation parameters.
00192 *
00193 * Function return value:
00194 *             int       Status return value:
00195 *                         0: Success.
00196 *                         1: Null spcprm pointer passed.
00197 *
00198 *
00199 * spcfree() - Destructor for the spcprm struct
00200 * --------------------------------------------
00201 * spcfree() frees any memory that may have been allocated to store an error
00202 * message in the spcprm struct.
00203 *
00204 * Given:
00205 *   spc       struct spcprm*
00206 *                       Spectral transformation parameters.
00207 *
00208 * Function return value:
00209 *             int       Status return value:
00210 *                         0: Success.
00211 *                         1: Null spcprm pointer passed.
00212 *
00213 *
00214 * spcsize() - Compute the size of a spcprm struct
00215 * ----------------------------------------------
00216 * spcsize() computes the full size of a spcprm struct, including allocated
00217 * memory.
00218 *
00219 * Given:
00220 *   spc       const struct spcprm*
00221 *                       Spectral transformation parameters.
00222 *
00223 *                       If NULL, the base size of the struct and the allocated
00224 *                       size are both set to zero.
00225 *
00226 * Returned:
00227 *   sizes     int[2]    The first element is the base size of the struct as
00228 *                       returned by sizeof(struct spcprm).  The second element
00229 *                       is the total allocated size, in bytes.  This figure
00230 *                       includes memory allocated for the constituent struct,
00231 *                       spcprm::err.
00232 *
00233 *                       It is not an error for the struct not to have been set
00234 *                       up via spcset().
00235 *
00236 * Function return value:
00237 *             int       Status return value:
00238 *                         0: Success.
```

```
00239 *
00240 *
00241 * spcprt() - Print routine for the spcprm struct
00242 * ---------------------------------------------
00243 * spcprt() prints the contents of a spcprm struct using wcsprintf().  Mainly
00244 * intended for diagnostic purposes.
00245 *
00246 * Given:
00247 *   spc       const struct spcprm*
00248 *                       Spectral transformation parameters.
00249 *
00250 * Function return value:
00251 *             int       Status return value:
00252 *                         0: Success.
00253 *                         1: Null spcprm pointer passed.
00254 *
00255 *
00256 * spcperr() - Print error messages from a spcprm struct
00257 * ----------------------------------------------------
00258 * spcperr() prints the error message(s) (if any) stored in a spcprm struct.
00259 * If there are no errors then nothing is printed.  It uses wcserr_prt(), q.v.
00260 *
00261 * Given:
00262 *   spc       const struct spcprm*
00263 *                       Spectral transformation parameters.
00264 *
00265 *   prefix    const char *
00266 *                       If non-NULL, each output line will be prefixed with
00267 *                       this string.
00268 *
00269 * Function return value:
00270 *             int       Status return value:
00271 *                         0: Success.
00272 *                         1: Null spcprm pointer passed.
00273 *
00274 *
00275 * spcset() - Setup routine for the spcprm struct
00276 * ---------------------------------------------
00277 * spcset() sets up a spcprm struct according to information supplied within
00278 * it.
00279 *
00280 * Note that this routine need not be called directly; it will be invoked by
00281 * spcx2s() and spcs2x() if spcprm::flag is anything other than a predefined
00282 * magic value.
00283 *
00284 * Given and returned:
00285 *   spc       struct spcprm*
00286 *                       Spectral transformation parameters.
00287 *
00288 * Function return value:
00289 *             int       Status return value:
00290 *                         0: Success.
00291 *                         1: Null spcprm pointer passed.
00292 *                         2: Invalid spectral parameters.
00293 *
00294 *                       For returns > 1, a detailed error message is set in
00295 *                       spcprm::err if enabled, see wcserr_enable().
00296 *
00297 *
00298 * spcx2s() - Transform to spectral coordinates
00299 * --------------------------------------------
00300 * spcx2s() transforms intermediate world coordinates to spectral coordinates.
00301 *
00302 * Given and returned:
00303 *   spc       struct spcprm*
00304 *                       Spectral transformation parameters.
00305 *
00306 * Given:
00307 *   nx        int       Vector length.
00308 *
00309 *   sx        int       Vector stride.
00310 *
00311 *   sspec     int       Vector stride.
00312 *
00313 *   x         const double[]
00314 *                       Intermediate world coordinates, in SI units.
00315 *
00316 * Returned:
00317 *   spec      double[]  Spectral coordinates, in SI units.
00318 *
00319 *   stat      int[]     Status return value status for each vector element:
00320 *                         0: Success.
00321 *                         1: Invalid value of x.
00322 *
00323 * Function return value:
00324 *             int       Status return value:
00325 *                         0: Success.
```

```
00326 *                         1: Null spcprm pointer passed.
00327 *                         2: Invalid spectral parameters.
00328 *                         3: One or more of the x coordinates were invalid,
00329 *                            as indicated by the stat vector.
00330 *
00331 *                       For returns > 1, a detailed error message is set in
00332 *                       spcprm::err if enabled, see wcserr_enable().
00333 *
00334 *
00335 * spcs2x() - Transform spectral coordinates
00336 * -----------------------------------------
00337 * spcs2x() transforms spectral world coordinates to intermediate world
00338 * coordinates.
00339 *
00340 * Given and returned:
00341 *   spc       struct spcprm*
00342 *                       Spectral transformation parameters.
00343 *
00344 * Given:
00345 *   nspec     int       Vector length.
00346 *
00347 *   sspec     int       Vector stride.
00348 *
00349 *   sx        int       Vector stride.
00350 *
00351 *   spec      const double[]
00352 *                       Spectral coordinates, in SI units.
00353 *
00354 * Returned:
00355 *   x         double[]  Intermediate world coordinates, in SI units.
00356 *
00357 *   stat      int[]     Status return value status for each vector element:
00358 *                         0: Success.
00359 *                         1: Invalid value of spec.
00360 *
00361 * Function return value:
00362 *             int       Status return value:
00363 *                         0: Success.
00364 *                         1: Null spcprm pointer passed.
00365 *                         2: Invalid spectral parameters.
00366 *                         4: One or more of the spec coordinates were
00367 *                            invalid, as indicated by the stat vector.
00368 *
00369 *                       For returns > 1, a detailed error message is set in
00370 *                       spcprm::err if enabled, see wcserr_enable().
00371 *
00372 *
00373 * spctype() - Spectral CTYPEia keyword analysis
00374 * ---------------------------------------------
00375 * spctype() checks whether a CTYPEia keyvalue is a valid spectral axis type
00376 * and if so returns information derived from it relating to the associated S-,
00377 * P-, and X-type spectral variables (see explanation above).
00378 *
00379 * The return arguments are guaranteed not be modified if CTYPEia is not a
00380 * valid spectral type; zero-pointers may be specified for any that are not of
00381 * interest.
00382 *
00383 * A deprecated form of this function, spctyp(), lacks the wcserr** parameter.
00384 *
00385 * Given:
00386 *   ctype     const char[9]
00387 *                       The CTYPEia keyvalue, (eight characters with null
00388 *                       termination).
00389 *
00390 * Returned:
00391 *   stype     char[]    The four-letter name of the S-type spectral variable
00392 *                       copied or translated from ctype.  If a non-zero
00393 *                       pointer is given, the array must accomodate a null-
00394 *                       terminated string of length 5.
00395 *
00396 *   scode     char[]    The three-letter spectral algorithm code copied or
00397 *                       translated from ctype.  Logarithmic ('LOG') and
00398 *                       tabular ('TAB') codes are also recognized.  If a
00399 *                       non-zero pointer is given, the array must accomodate a
00400 *                       null-terminated string of length 4.
00401 *
00402 *   sname     char[]    Descriptive name of the S-type spectral variable.
00403 *                       If a non-zero pointer is given, the array must
00404 *                       accomodate a null-terminated string of length 22.
00405 *
00406 *   units     char[]    SI units of the S-type spectral variable.  If a
00407 *                       non-zero pointer is given, the array must accomodate a
00408 *                       null-terminated string of length 8.
00409 *
00410 *   ptype     char*     Character code for the P-type spectral variable
00411 *                       derived from ctype, one of 'F', 'W', 'A', or 'V'.
00412 *
```

```
00413 *   xtype     char*     Character code for the X-type spectral variable
00414 *                       derived from ctype, one of 'F', 'W', 'A', or 'V'.
00415 *                       Also, 'w' and 'a' are synonymous to 'W' and 'A' for
00416 *                       grisms in vacuo and air respectively.  Set to 'L' or
00417 *                       'T' for logarithmic ('LOG') and tabular ('TAB') axes.
00418 *
00419 *   restreq   int*      Multivalued flag that indicates whether rest
00420 *                       frequency or wavelength is required to compute
00421 *                       spectral variables for this CTYPEia:
00422 *                         0: Not required.
00423 *                         1: Required for the conversion between S- and
00424 *                            P-types (e.g. 'ZOPT-F2W').
00425 *                         2: Required for the conversion between P- and
00426 *                            X-types (e.g. 'BETA-W2V').
00427 *                         3: Required for the conversion between S- and
00428 *                            P-types, and between P- and X-types, but not
00429 *                            between S- and X-types (this applies only for
00430 *                            'VRAD-V2F', 'VOPT-V2W', and 'ZOPT-V2W').
00431 *                        Thus the rest frequency or wavelength is required for
00432 *                        spectral coordinate computations (i.e. between S- and
00433 *                        X-types) only if restreq%3 != 0.
00434 *
00435 *   err       struct wcserr **
00436 *                       If enabled, for function return values > 1, this
00437 *                       struct will contain a detailed error message, see
00438 *                       wcserr_enable().  May be NULL if an error message is
00439 *                       not desired.  Otherwise, the user is responsible for
00440 *                       deleting the memory allocated for the wcserr struct.
00441 *
00442 * Function return value:
00443 *             int       Status return value:
00444 *                         0: Success.
00445 *                         2: Invalid spectral parameters (not a spectral
00446 *                            CTYPEia).
00447 *
00448 *
00449 * spcspxe() - Spectral keyword analysis
00450 * -------------------------------------
00451 * spcspxe() analyses the CTYPEia and CRVALia FITS spectral axis keyword values
00452 * and returns information about the associated X-type spectral variable.
00453 *
00454 * A deprecated form of this function, spcspx(), lacks the wcserr** parameter.
00455 *
00456 * Given:
00457 *   ctypeS    const char[9]
00458 *                       Spectral axis type, i.e. the CTYPEia keyvalue, (eight
00459 *                       characters with null termination).  For non-grism
00460 *                       axes, the character code for the P-type spectral
00461 *                       variable in the algorithm code (i.e. the eighth
00462 *                       character of CTYPEia) may be set to '?' (it will not
00463 *                       be reset).
00464 *
00465 *   crvalS    double    Value of the S-type spectral variable at the reference
00466 *                       point, i.e. the CRVALia keyvalue, SI units.
00467 *
00468 *   restfrq,
00469 *   restwav   double    Rest frequency [Hz] and rest wavelength in vacuo [m],
00470 *                       only one of which need be given, the other should be
00471 *                       set to zero.
00472 *
00473 * Returned:
00474 *   ptype     char*     Character code for the P-type spectral variable
00475 *                       derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
00476 *
00477 *   xtype     char*     Character code for the X-type spectral variable
00478 *                       derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
00479 *                       Also, 'w' and 'a' are synonymous to 'W' and 'A' for
00480 *                       grisms in vacuo and air respectively; crvalX and dXdS
00481 *                       (see below) will conform to these.
00482 *
00483 *   restreq   int*      Multivalued flag that indicates whether rest frequency
00484 *                       or wavelength is required to compute spectral
00485 *                       variables for this CTYPEia, as for spctype().
00486 *
00487 *   crvalX    double*   Value of the X-type spectral variable at the reference
00488 *                       point, SI units.
00489 *
00490 *   dXdS      double*   The derivative, dX/dS, evaluated at the reference
00491 *                       point, SI units.  Multiply the CDELTia keyvalue by
00492 *                       this to get the pixel spacing in the X-type spectral
00493 *                       coordinate.
00494 *
00495 *   err       struct wcserr **
00496 *                       If enabled, for function return values > 1, this
00497 *                       struct will contain a detailed error message, see
00498 *                       wcserr_enable().  May be NULL if an error message is
00499 *                       not desired.  Otherwise, the user is responsible for
```

```
00500 *                      deleting the memory allocated for the wcserr struct.
00501 *
00502 * Function return value:
00503 *             int      Status return value:
00504 *                        0: Success.
00505 *                        2: Invalid spectral parameters.
00506 *
00507 *
00508 * spcxpse() - Spectral keyword synthesis
00509 * -------------------------------------
00510 * spcxpse(), for the spectral axis type specified and the value provided for
00511 * the X-type spectral variable at the reference point, deduces the value of
00512 * the FITS spectral axis keyword CRVALia and also the derivative dS/dX which
00513 * may be used to compute CDELTia.  See above for an explanation of the S-,
00514 * P-, and X-type spectral variables.
00515 *
00516 * A deprecated form of this function, spcxps(), lacks the wcserr** parameter.
00517 *
00518 * Given:
00519 *   ctypeS    const char[9]
00520 *                      The required spectral axis type, i.e. the CTYPEia
00521 *                      keyvalue, (eight characters with null termination).
00522 *                      For non-grism axes, the character code for the P-type
00523 *                      spectral variable in the algorithm code (i.e. the
00524 *                      eighth character of CTYPEia) may be set to '?' (it
00525 *                      will not be reset).
00526 *
00527 *   crvalX    double   Value of the X-type spectral variable at the reference
00528 *                      point (N.B. NOT the CRVALia keyvalue), SI units.
00529 *
00530 *   restfrq,
00531 *   restwav   double   Rest frequency [Hz] and rest wavelength in vacuo [m],
00532 *                      only one of which need be given, the other should be
00533 *                      set to zero.
00534 *
00535 * Returned:
00536 *   ptype     char*    Character code for the P-type spectral variable
00537 *                      derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
00538 *
00539 *   xtype     char*    Character code for the X-type spectral variable
00540 *                      derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
00541 *                      Also, 'w' and 'a' are synonymous to 'W' and 'A' for
00542 *                      grisms; crvalX and cdeltX must conform to these.
00543 *
00544 *   restreq   int*     Multivalued flag that indicates whether rest frequency
00545 *                      or wavelength is required to compute spectral
00546 *                      variables for this CTYPEia, as for spctype().
00547 *
00548 *   crvalS    double*  Value of the S-type spectral variable at the reference
00549 *                      point (i.e. the appropriate CRVALia keyvalue), SI
00550 *                      units.
00551 *
00552 *   dSdX      double*  The derivative, dS/dX, evaluated at the reference
00553 *                      point, SI units.  Multiply this by the pixel spacing
00554 *                      in the X-type spectral coordinate to get the CDELTia
00555 *                      keyvalue.
00556 *
00557 *   err       struct wcserr **
00558 *                      If enabled, for function return values > 1, this
00559 *                      struct will contain a detailed error message, see
00560 *                      wcserr_enable().  May be NULL if an error message is
00561 *                      not desired.  Otherwise, the user is responsible for
00562 *                      deleting the memory allocated for the wcserr struct.
00563 *
00564 * Function return value:
00565 *             int      Status return value:
00566 *                        0: Success.
00567 *                        2: Invalid spectral parameters.
00568 *
00569 *
00570 * spctrne() - Spectral keyword translation
00571 * ----------------------------------------
00572 * spctrne() translates a set of FITS spectral axis keywords into the
00573 * corresponding set for the specified spectral axis type.  For example, a
00574 * 'FREQ' axis may be translated into 'ZOPT-F2W' and vice versa.
00575 *
00576 * A deprecated form of this function, spctrn(), lacks the wcserr** parameter.
00577 *
00578 * Given:
00579 *   ctypeS1   const char[9]
00580 *                      Spectral axis type, i.e. the CTYPEia keyvalue, (eight
00581 *                      characters with null termination).  For non-grism
00582 *                      axes, the character code for the P-type spectral
00583 *                      variable in the algorithm code (i.e. the eighth
00584 *                      character of CTYPEia) may be set to '?' (it will not
00585 *                      be reset).
00586 *
```

```
00587 *   crvalS1   double    Value of the S-type spectral variable at the reference
00588 *                       point, i.e. the CRVALia keyvalue, SI units.
00589 *
00590 *   cdeltS1   double    Increment of the S-type spectral variable at the
00591 *                       reference point, SI units.
00592 *
00593 *   restfrq,
00594 *   restwav   double    Rest frequency [Hz] and rest wavelength in vacuo [m],
00595 *                       only one of which need be given, the other should be
00596 *                       set to zero.  Neither are required if the translation
00597 *                       is between wave-characteristic types, or between
00598 *                       velocity-characteristic types.  E.g., required for
00599 *                       'FREQ'     -> 'ZOPT-F2W', but not required for
00600 *                       'VELO-F2V' -> 'ZOPT-F2W'.
00601 *
00602 * Given and returned:
00603 *   ctypeS2   char[9]   Required spectral axis type (eight characters with
00604 *                       null termination).  The first four characters are
00605 *                       required to be given and are never modified.  The
00606 *                       remaining four, the algorithm code, are completely
00607 *                       determined by, and must be consistent with, ctypeS1
00608 *                       and the first four characters of ctypeS2.  A non-zero
00609 *                       status value will be returned if they are inconsistent
00610 *                       (see below).  However, if the final three characters
00611 *                       are specified as "???", or if just the eighth
00612 *                       character is specified as '?', the correct algorithm
00613 *                       code will be substituted (applies for grism axes as
00614 *                       well as non-grism).
00615 *
00616 * Returned:
00617 *   crvalS2   double*   Value of the new S-type spectral variable at the
00618 *                       reference point, i.e. the new CRVALia keyvalue, SI
00619 *                       units.
00620 *
00621 *   cdeltS2   double*   Increment of the new S-type spectral variable at the
00622 *                       reference point, i.e. the new CDELTia keyvalue, SI
00623 *                       units.
00624 *
00625 *   err       struct wcserr **
00626 *                       If enabled, for function return values > 1, this
00627 *                       struct will contain a detailed error message, see
00628 *                       wcserr_enable().  May be NULL if an error message is
00629 *                       not desired.  Otherwise, the user is responsible for
00630 *                       deleting the memory allocated for the wcserr struct.
00631 *
00632 * Function return value:
00633 *             int       Status return value:
00634 *                         0: Success.
00635 *                         2: Invalid spectral parameters.
00636 *
00637 *                       A status value of 2 will be returned if restfrq or
00638 *                       restwav are not specified when required, or if ctypeS1
00639 *                       or ctypeS2 are self-inconsistent, or have different
00640 *                       spectral X-type variables.
00641 *
00642 *
00643 * spcaips() - Translate AIPS-convention spectral keywords
00644 * -------------------------------------------------------
00645 * spcaips() translates AIPS-convention spectral CTYPEia and VELREF keyvalues.
00646 *
00647 * Given:
00648 *   ctypeA    const char[9]
00649 *                       CTYPEia keyvalue possibly containing an
00650 *                       AIPS-convention spectral code (eight characters, need
00651 *                       not be null-terminated).
00652 *
00653 *   velref    int       AIPS-convention VELREF code.  It has the following
00654 *                       integer values:
00655 *                         1: LSR kinematic, originally described simply as
00656 *                            "LSR" without distinction between the kinematic
00657 *                            and dynamic definitions.
00658 *                         2: Barycentric, originally described as "HEL"
00659 *                            meaning heliocentric.
00660 *                         3: Topocentric, originally described as "OBS"
00661 *                            meaning geocentric but widely interpreted as
00662 *                            topocentric.
00663 *                       AIPS++ extensions to VELREF are also recognized:
00664 *                         4: LSR dynamic.
00665 *                         5: Geocentric.
00666 *                         6: Source rest frame.
00667 *                         7: Galactocentric.
00668 *
00669 *                       For an AIPS 'VELO' axis, a radio convention velocity
00670 *                       (VRAD) is denoted by adding 256 to VELREF, otherwise
00671 *                       an optical velocity (VOPT) is indicated (this is not
00672 *                       applicable to 'FREQ' or 'FELO' axes).  Setting velref
00673 *                       to 0 or 256 chooses between optical and radio velocity
```

```
00674 *                       without specifying a Doppler frame, provided that a
00675 *                       frame is encoded in ctypeA.  If not, i.e. for
00676 *                       ctypeA = 'VELO', ctype will be returned as 'VELO'.
00677 *
00678 *                       VELREF takes precedence over CTYPEia in defining the
00679 *                       Doppler frame, e.g.
00680 *
00681 =                         ctypeA = 'VELO-HEL'
00682 =                         velref = 1
00683 *
00684 *                       returns ctype = 'VOPT' with specsys set to 'LSRK'.
00685 *
00686 *                       If omitted from the header, the default value of
00687 *                       VELREF is 0.
00688 *
00689 * Returned:
00690 *   ctype     char[9]   Translated CTYPEia keyvalue, or a copy of ctypeA if no
00691 *                       translation was performed (in which case any trailing
00692 *                       blanks in ctypeA will be replaced with nulls).
00693 *
00694 *   specsys   char[9]   Doppler reference frame indicated by VELREF or else
00695 *                       by CTYPEia with value corresponding to the SPECSYS
00696 *                       keyvalue in the FITS WCS standard.  May be returned
00697 *                       blank if neither specifies a Doppler frame, e.g.
00698 *                       ctypeA = 'FELO' and velref%256 == 0.
00699 *
00700 * Function return value:
00701 *             int       Status return value:
00702 *                        -1: No translation required (not an error).
00703 *                         0: Success.
00704 *                         2: Invalid value of VELREF.
00705 *
00706 *
00707 * spcprm struct - Spectral transformation parameters
00708 * ------------------------------------------------
00709 * The spcprm struct contains information required to transform spectral
00710 * coordinates.  It consists of certain members that must be set by the user
00711 * ("given") and others that are set by the WCSLIB routines ("returned").  Some
00712 * of the latter are supplied for informational purposes while others are for
00713 * internal use only.
00714 *
00715 *   int flag
00716 *     (Given and returned) This flag must be set to zero whenever any of the
00717 *     following spcprm structure members are set or changed:
00718 *
00719 *       - spcprm::type,
00720 *       - spcprm::code,
00721 *       - spcprm::crval,
00722 *       - spcprm::restfrq,
00723 *       - spcprm::restwav,
00724 *       - spcprm::pv[].
00725 *
00726 *     This signals the initialization routine, spcset(), to recompute the
00727 *     returned members of the spcprm struct.  spcset() will reset flag to
00728 *     indicate that this has been done.
00729 *
00730 *   char type[8]
00731 *     (Given) Four-letter spectral variable type, e.g "ZOPT" for
00732 *     CTYPEia = 'ZOPT-F2W'.  (Declared as char[8] for alignment reasons.)
00733 *
00734 *   char code[4]
00735 *     (Given) Three-letter spectral algorithm code, e.g "F2W" for
00736 *     CTYPEia = 'ZOPT-F2W'.
00737 *
00738 *   double crval
00739 *     (Given) Reference value (CRVALia), SI units.
00740 *
00741 *   double restfrq
00742 *     (Given) The rest frequency [Hz], and ...
00743 *
00744 *   double restwav
00745 *     (Given) ... the rest wavelength in vacuo [m], only one of which need be
00746 *     given, the other should be set to zero.  Neither are required if the
00747 *     X and S spectral variables are both wave-characteristic, or both
00748 *     velocity-characteristic, types.
00749 *
00750 *   double pv[7]
00751 *     (Given) Grism parameters for 'GRI' and 'GRA' algorithm codes:
00752 *       - 0: G, grating ruling density.
00753 *       - 1: m, interference order.
00754 *       - 2: alpha, angle of incidence [deg].
00755 *       - 3: n_r, refractive index at the reference wavelength, lambda_r.
00756 *       - 4: n'_r, dn/dlambda at the reference wavelength, lambda_r (/m).
00757 *       - 5: epsilon, grating tilt angle [deg].
00758 *       - 6: theta, detector tilt angle [deg].
00759 *
00760 * The remaining members of the spcprm struct are maintained by spcset() and
```

```
00761 * must not be modified elsewhere:
00762 *
00763 *   double w[6]
00764 *     (Returned) Intermediate values:
00765 *       - 0: Rest frequency or wavelength (SI).

6.17 sph.h File Reference

Functions

- int sphx2s (const double eul[5], int nphi, int ntheta, int spt, int sxy, const double phi[ ], const double theta[ ], double lng[ ], double lat[ ])

  Rotation in the pixel-to-world direction.
- int sphs2x (const double eul[5], int nlng, int nlat, int sll, int spt, const double lng[ ], const double lat[ ], double phi[ ], double theta[ ])

  Rotation in the world-to-pixel direction.
- int sphdpa (int nfield, double lng0, double lat0, const double lng[ ], const double lat[ ], double dist[ ], double pa[ ])

  Compute angular distance and position angle.
- int sphpad (int nfield, double lng0, double lat0, const double dist[ ], const double pa[ ], double lng[ ], double lat[ ])

  Compute field points offset from a given point.

6.17.1 Detailed Description

Routines in this suite implement the spherical coordinate transformations defined by the FITS World Coordinate System (WCS) standard
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

The transformations are implemented via separate functions, sphx2s() and sphs2x(), for the spherical rotation in each direction.

A utility function, sphdpa(), computes the angular distances and position angles from a given point on the sky to a number of other points. sphpad() does the complementary operation - computes the coordinates of points offset by the given angular distances and position angles from a given point on the sky.

6.17.2 Function Documentation

sphx2s()

```
int sphx2s (
            const double eul[5],
            int nphi,
            int ntheta,
            int spt,
            int sxy,
```

```
            const double phi[],
            const double theta[],
            double lng[],
            double lat[] )
```

Rotation in the pixel-to-world direction.

sphx2s() transforms native coordinates of a projection to celestial coordinates.

Parameters

in	*eul*	Euler angles for the transformation: • 0: Celestial longitude of the native pole [deg]. • 1: Celestial colatitude of the native pole, or native colatitude of the celestial pole [deg]. • 2: Native longitude of the celestial pole [deg]. • 3: cos(eul[1]) • 4: sin(eul[1])
in	*nphi,ntheta*	Vector lengths.
in	*spt,sxy*	Vector strides.
in	*phi,theta*	Longitude and latitude in the native coordinate system of the projection [deg].
out	*lng,lat*	Celestial longitude and latitude [deg]. These may refer to the same storage as *phi* and *theta* respectively.

Returns

Status return value:

- 0: Success.

sphs2x()

```
int sphs2x (
            const double eul[5],
            int nlng,
            int nlat,
            int sll,
            int spt,
            const double lng[],
            const double lat[],
            double phi[],
            double theta[] )
```

Rotation in the world-to-pixel direction.

sphs2x() transforms celestial coordinates to the native coordinates of a projection.

Parameters

in	*eul*	Euler angles for the transformation: • 0: Celestial longitude of the native pole [deg]. • 1: Celestial colatitude of the native pole, or native colatitude of the celestial pole [deg]. • 2: Native longitude of the celestial pole [deg]. • 3: cos(eul[1]) • 4: sin(eul[1])
in	*nlng,nlat*	Vector lengths.
in	*sll,spt*	Vector strides.
in	*lng,lat*	Celestial longitude and latitude [deg].
out	*phi,theta*	Longitude and latitude in the native coordinate system of the projection [deg]. These may refer to the same storage as *lng* and *lat* respectively.

Returns

Status return value:

- 0: Success.

sphdpa()

```
int sphdpa (
            int nfield,
            double lng0,
            double lat0,
            const double lng[],
            const double lat[],
            double dist[],
            double pa[] )
```

Compute angular distance and position angle.

sphdpa() computes the angular distance and generalized position angle (see notes) from a "reference" point to a number of "field" points on the sphere. The points must be specified consistently in any spherical coordinate system.

sphdpa() is complementary to sphpad().

Parameters

in	*nfield*	The number of field points.
in	*lng0,lat0*	Spherical coordinates of the reference point [deg].
in	*lng,lat*	Spherical coordinates of the field points [deg].
out	*dist,pa*	Angular distances and position angles [deg]. These may refer to the same storage as *lng* and *lat* respectively.

Returns

Status return value:

- 0: Success.

Notes:
1. **sphdpa**() uses sphs2x() to rotate coordinates so that the reference point is at the north pole of the new system with the north pole of the old system at zero longitude in the new. The Euler angles required by sphs2x() for this rotation are

```
eul[0] = lng0;
eul[1] = 90.0 - lat0;
eul[2] =  0.0;
```

The angular distance and generalized position angle are readily obtained from the longitude and latitude of the field point in the new system. This applies even if the reference point is at one of the poles, in which case the "position angle" returned is as would be computed for a reference point at $(\alpha_0, +90^\circ - \epsilon)$ or $(\alpha_0, -90^\circ + \epsilon)$, in the limit as ϵ goes to zero.

It is evident that the coordinate system in which the two points are expressed is irrelevant to the determination of the angular separation between the points. However, this is not true of the generalized position angle.

The generalized position angle is here defined as the angle of intersection of the great circle containing the reference and field points with that containing the reference point and the pole. It has its normal meaning when the the reference and field points are specified in equatorial coordinates (right ascension and declination).

Interchanging the reference and field points changes the position angle in a non-intuitive way (because the sum of the angles of a spherical triangle normally exceeds 180°).

The position angle is undefined if the reference and field points are coincident or antipodal. This may be detected by checking for a distance of 0° or 180° (within rounding tolerance). **sphdpa**() will return an arbitrary position angle in such circumstances.

sphpad()

```
int sphpad (
             int nfield,
             double lng0,
             double lat0,
             const double dist[],
             const double pa[],
             double lng[],
             double lat[] )
```

Compute field points offset from a given point.

sphpad() computes the coordinates of a set of points that are offset by the specified angular distances and position angles from a given "reference" point on the sky. The distances and position angles must be specified consistently in any spherical coordinate system.

sphpad() is complementary to sphdpa().

Parameters

in	*nfield*	The number of field points.
in	*lng0,lat0*	Spherical coordinates of the reference point [deg].
in	*dist,pa*	Angular distances and position angles [deg].
out	*lng,lat*	Spherical coordinates of the field points [deg]. These may refer to the same storage as *dist* and *pa* respectively.

Returns

Status return value:

- 0: Success.

Notes:

1. **sphpad**() is implemented analogously to sphdpa() although using sphx2s() for the inverse transformation. In particular, when the reference point is at one of the poles, "position angle" is interpreted as though the reference point was at $(\alpha_0, +90° - \epsilon)$ or $(\alpha_0, -90° + \epsilon)$, in the limit as ϵ goes to zero.

Applying **sphpad**() with the distances and position angles computed by sphdpa() should return the original field points.

00071 *   phi,theta const double[]
00072 *                        Longitude and latitude in the native coordinate
00073 *                        system of the projection [deg].
00074 *
00075 * Returned:
00076 *   lng,lat   double[]  Celestial longitude and latitude [deg].  These may
00077 *                        refer to the same storage as phi and theta
00078 *                        respectively.
00079 *
00080 * Function return value:
00081 *             int       Status return value:
00082 *                         0: Success.
00083 *
00084 *
00085 * sphs2x() - Rotation in the world-to-pixel direction
00086 * ---------------------------------------------------
00087 * sphs2x() transforms celestial coordinates to the native coordinates of a
00088 * projection.
00089 *
00090 * Given:
00091 *   eul       const double[5]
00092 *                        Euler angles for the transformation:
00093 *                          0: Celestial longitude of the native pole [deg].
00094 *                          1: Celestial colatitude of the native pole, or
00095 *                             native colatitude of the celestial pole [deg].
00096 *                          2: Native longitude of the celestial pole [deg].
00097 *                          3: cos(eul[1])
00098 *                          4: sin(eul[1])
00099 *
00100 *   nlng,nlat int       Vector lengths.
00101 *
00102 *   sll,spt   int       Vector strides.
00103 *
00104 *   lng,lat   const double[]
00105 *                        Celestial longitude and latitude [deg].
00106 *
00107 * Returned:
00108 *   phi,theta double[]  Longitude and latitude in the native coordinate system
00109 *                        of the projection [deg].  These may refer to the same
00110 *                        storage as lng and lat respectively.
00111 *
00112 * Function return value:
00113 *             int       Status return value:
00114 *                         0: Success.
00115 *
00116 *
00117 * sphdpa() - Compute angular distance and position angle
00118 * ------------------------------------------------------
00119 * sphdpa() computes the angular distance and generalized position angle (see
00120 * notes) from a "reference" point to a number of "field" points on the sphere.
00121 * The points must be specified consistently in any spherical coordinate
00122 * system.
00123 *
00124 * sphdpa() is complementary to sphpad().
00125 *
00126 * Given:
00127 *   nfield    int       The number of field points.
00128 *
00129 *   lng0,lat0 double    Spherical coordinates of the reference point [deg].
00130 *
00131 *   lng,lat   const double[]
00132 *                        Spherical coordinates of the field points [deg].
00133 *
00134 * Returned:
00135 *   dist,pa   double[]  Angular distances and position angles [deg].  These
00136 *                        may refer to the same storage as lng and lat
00137 *                        respectively.
00138 *
00139 * Function return value:
00140 *             int       Status return value:
00141 *                         0: Success.
00142 *
```

```
00143 * Notes:
00144 *   1. sphdpa() uses sphs2x() to rotate coordinates so that the reference
00145 *      point is at the north pole of the new system with the north pole of the
00146 *      old system at zero longitude in the new.  The Euler angles required by
00147 *      sphs2x() for this rotation are
00148 *
00149 =        eul[0] = lng0;
00150 =        eul[1] = 90.0 - lat0;
00151 =        eul[2] =  0.0;
00152 *
00153 *      The angular distance and generalized position angle are readily
00154 *      obtained from the longitude and latitude of the field point in the new
00155 *      system.  This applies even if the reference point is at one of the
00156 *      poles, in which case the "position angle" returned is as would be
00157 *      computed for a reference point at (lng0,+90-epsilon) or
00158 *      (lng0,-90+epsilon), in the limit as epsilon goes to zero.
00159 *
00160 *      It is evident that the coordinate system in which the two points are
00161 *      expressed is irrelevant to the determination of the angular separation
00162 *      between the points.  However, this is not true of the generalized
00163 *      position angle.
00164 *
00165 *      The generalized position angle is here defined as the angle of
00166 *      intersection of the great circle containing the reference and field
00167 *      points with that containing the reference point and the pole.  It has
00168 *      its normal meaning when the the reference and field points are
00169 *      specified in equatorial coordinates (right ascension and declination).
00170 *
00171 *      Interchanging the reference and field points changes the position angle
00172 *      in a non-intuitive way (because the sum of the angles of a spherical
00173 *      triangle normally exceeds 180 degrees).
00174 *
00175 *      The position angle is undefined if the reference and field points are
00176 *      coincident or antipodal.  This may be detected by checking for a
00177 *      distance of 0 or 180 degrees (within rounding tolerance).  sphdpa()
00178 *      will return an arbitrary position angle in such circumstances.
00179 *
00180 *
00181 * sphpad() - Compute field points offset from a given point
00182 * ---------------------------------------------------------
00183 * sphpad() computes the coordinates of a set of points that are offset by the
00184 * specified angular distances and position angles from a given "reference"
00185 * point on the sky.  The distances and position angles must be specified
00186 * consistently in any spherical coordinate system.
00187 *
00188 * sphpad() is complementary to sphdpa().
00189 *
00190 * Given:
00191 *   nfield    int       The number of field points.
00192 *
00193 *   lng0,lat0 double    Spherical coordinates of the reference point [deg].
00194 *
00195 *   dist,pa   const double[]
00196 *                       Angular distances and position angles [deg].
00197 *
00198 * Returned:
00199 *   lng,lat   double[]  Spherical coordinates of the field points [deg].
00200 *                       These may refer to the same storage as dist and pa
00201 *                       respectively.
00202 *
00203 * Function return value:
00204 *             int       Status return value:
00205 *                         0: Success.
00206 *
00207 * Notes:
00208 *   1: sphpad() is implemented analogously to sphdpa() although using sphx2s()
00209 *      for the inverse transformation.  In particular, when the reference
00210 *      point is at one of the poles, "position angle" is interpreted as though
00211 *      the reference point was at (lng0,+90-epsilon) or (lng0,-90+epsilon), in
00212 *      the limit as epsilon goes to zero.
00213 *
00214 *   Applying sphpad() with the distances and position angles computed by
00215 *   sphdpa() should return the original field points.
00216 *
00217 *===========================================================================*/

6.19.1 Detailed Description

Routines in this suite implement the spectral coordinate systems recognized by the FITS World Coordinate System (WCS) standard, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)
```

specx() is a scalar routine that, given one spectral variable (e.g. frequency), computes all the others (e.g. wavelength, velocity, etc.) plus the required derivatives of each with respect to the others. The results are returned in the spxprm struct.

spxperr() prints the error message(s) (if any) stored in a spxprm struct.

The remaining routines are all vector conversions from one spectral variable to another. The API of these functions only differ in whether the rest frequency or wavelength need be supplied.

Non-linear:

- freqwave() frequency -> vacuum wavelength
- wavefreq() vacuum wavelength -> frequency
- freqawav() frequency -> air wavelength
- awavfreq() air wavelength -> frequency
- freqvelo() frequency -> relativistic velocity
- velofreq() relativistic velocity -> frequency
- waveawav() vacuum wavelength -> air wavelength
- awavwave() air wavelength -> vacuum wavelength
- wavevelo() vacuum wavelength -> relativistic velocity
- velowave() relativistic velocity -> vacuum wavelength
- awavvelo() air wavelength -> relativistic velocity
- veloawav() relativistic velocity -> air wavelength

Linear:

- freqafrq() frequency -> angular frequency
- afrqfreq() angular frequency -> frequency
- freqener() frequency -> energy
- enerfreq() energy -> frequency
- freqwavn() frequency -> wave number
- wavnfreq() wave number -> frequency
- freqvrad() frequency -> radio velocity

- vradfreq() radio velocity -> frequency
- wavevopt() vacuum wavelength -> optical velocity
- voptwave() optical velocity -> vacuum wavelength
- wavezopt() vacuum wavelength -> redshift
- zoptwave() redshift -> vacuum wavelength
- velobeta() relativistic velocity -> beta ($\beta = v/c$)
- betavelo() beta ($\beta = v/c$) -> relativistic velocity

These are the workhorse routines, to be used for fast transformations. Conversions may be done "in place" by calling the routine with the output vector set to the input.

Air-to-vacuum wavelength conversion:
The air-to-vacuum wavelength conversion in early drafts of WCS Paper III cites Cox (ed., 2000, Allen's Astrophysical Quantities, AIP Press, Springer-Verlag, New York), which itself derives from Edlén (1953, Journal of the Optical Society of America, 43, 339). This is the IAU standard, adopted in 1957 and again in 1991. No more recent IAU resolution replaces this relation, and it is the one used by WCSLIB.

However, the Cox relation was replaced in later drafts of Paper III, and as eventually published, by the IUGG relation (1999, International Union of Geodesy and Geophysics, comptes rendus of the 22nd General Assembly, Birmingham UK, p111). There is a nearly constant ratio between the two, with IUGG/Cox = 1.000015 over most of the range between 200nm and 10,000nm.

The IUGG relation itself is derived from the work of Ciddor (1996, Applied Optics, 35, 1566), which is used directly by the Sloan Digital Sky Survey. It agrees closely with Cox; longwards of 2500nm, the ratio Ciddor/Cox is fixed at 1.000000021, decreasing only slightly, to 1.000000018, at 1000nm.

The Cox, IUGG, and Ciddor relations all accurately provide the wavelength dependence of the air-to-vacuum wavelength conversion. However, for full accuracy, the atmospheric temperature, pressure, and partial pressure of water vapour must be taken into account. These will determine a small, wavelength-independent scale factor and offset, which is not considered by WCS Paper III.

WCS Paper III is also silent on the question of the range of validity of the air-to-vacuum wavelength conversion. Cox's relation would appear to be valid in the range 200nm to 10,000nm. Both the Cox and the Ciddor relations have singularities below 200nm, with Cox's at 156nm and 83nm. WCSLIB checks neither the range of validity, nor for these singularities.

Argument checking:
The input spectral values are only checked for values that would result in floating point exceptions. In particular, negative frequencies and wavelengths are allowed, as are velocities greater than the speed of light. The same is true for the spectral parameters - rest frequency and wavelength.

Accuracy:
No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine tspec.c which accompanies this software.

6.19.2 Macro Definition Documentation

SPXLEN

```
#define SPXLEN (sizeof(struct spxprm)/sizeof(int))
```

Size of the spxprm struct in *int* units.

Size of the spxprm struct in *int* units, used by the Fortran wrappers.

SPX_ARGS

```
#define SPX_ARGS
```

Value:

```
    double param, int nspec, int instep, int outstep, \
    const double inspec[], double outspec[], int stat[]
```

For use in declaring spectral conversion function prototypes.

Preprocessor macro used for declaring spectral conversion function prototypes.

6.19.3 Enumeration Type Documentation

spx_errmsg

```
enum spx_errmsg
```

Enumerator

SPXERR_SUCCESS	
SPXERR_NULL_POINTER	
SPXERR_BAD_SPEC_PARAMS	
SPXERR_BAD_SPEC_VAR	
SPXERR_BAD_INSPEC_COORD	

6.19.4 Function Documentation

specx()

```
int specx (
            const char * type,
            double spec,
            double restfrq,
            double restwav,
            struct spxprm * specs )
```

Spectral cross conversions (scalar).

Given one spectral variable **specx**() computes all the others, plus the required derivatives of each with respect to the others.

Parameters

in	*type*	The type of spectral variable given by spec, **FREQ**, **AFRQ**, **ENER**, **WAVN**, **VRAD**, **WAVE**, **VOPT**, **ZOPT**, **AWAV**, **VELO**, or **BETA** (case sensitive).
in	*spec*	The spectral variable given, in SI units.
in	*restfrq,restwav*	Rest frequency [Hz] or rest wavelength in vacuo [m], only one of which need be given. The other should be set to zero. If both are zero, only a subset of the spectral variables can be computed, the remainder are set to zero. Specifically, given one of **FREQ**, **AFRQ**, **ENER**, **WAVN**, **WAVE**, or **AWAV** the others can be computed without knowledge of the rest frequency. Likewise, **VRAD**, **VOPT**, **ZOPT**, **VELO**, and **BETA**.
in,out	*specs*	Data structure containing all spectral variables and their derivatives, in SI units.

Returns

Status return value:

- 0: Success.
- 1: Null spxprm pointer passed.
- 2: Invalid spectral parameters.
- 3: Invalid spectral variable.

For returns $>$ 1, a detailed error message is set in spxprm::err if enabled, see wcserr_enable().

freqafrq(), afrqfreq(), freqener(), enerfreq(), freqwavn(), wavnfreq(), freqwave(), wavefreq(), freqawav(), awavfreq(), waveawav(), awavwave(), velobeta(), and betavelo() implement vector conversions between wave-like or velocity-like spectral types (i.e. conversions that do not need the rest frequency or wavelength). They all have the same API.

spxperr()

```
int spxperr (
            const struct spxprm * spx,
            const char * prefix )
```

Print error messages from a spxprm struct.

spxperr() prints the error message(s) (if any) stored in a spxprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*spx*	Spectral variables and their derivatives.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null spxprm pointer passed.

freqafrq()

```
int freqafrq (
            SPX_ARGS  )
```

Convert frequency to angular frequency (vector).

freqafrq() converts frequency to angular frequency.

Parameters

in	*param*	Ignored.
in	*nspec*	Vector length.

Parameters

in	*instep,outstep*	Vector strides.
in	*inspec*	Input spectral variables, in SI units.
out	*outspec*	Output spectral variables, in SI units.
out	*stat*	Status return value for each vector element: • 0: Success. • 1: Invalid value of inspec.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.
- 4: One or more of the inspec coordinates were invalid, as indicated by the stat vector.

afrqfreq()

```
int afrqfreq (
              SPX_ARGS  )
```

Convert angular frequency to frequency (vector).

afrqfreq() converts angular frequency to frequency.

See freqafrq() for a description of the API.

freqener()

```
int freqener (
              SPX_ARGS  )
```

Convert frequency to photon energy (vector).

freqener() converts frequency to photon energy.

See freqafrq() for a description of the API.

enerfreq()

```
int enerfreq (
              SPX_ARGS  )
```

Convert photon energy to frequency (vector).

enerfreq() converts photon energy to frequency.

See freqafrq() for a description of the API.

freqwavn()

```
int freqwavn (
              SPX_ARGS  )
```

Convert frequency to wave number (vector).

freqwavn() converts frequency to wave number.

See freqafrq() for a description of the API.

wavnfreq()

```
int wavnfreq (
              SPX_ARGS  )
```

Convert wave number to frequency (vector).

wavnfreq() converts wave number to frequency.

See freqafrq() for a description of the API.

freqwave()

```
int freqwave (
              SPX_ARGS  )
```

Convert frequency to vacuum wavelength (vector).

freqwave() converts frequency to vacuum wavelength.

See freqafrq() for a description of the API.

wavefreq()

```
int wavefreq (
              SPX_ARGS  )
```

Convert vacuum wavelength to frequency (vector).

wavefreq() converts vacuum wavelength to frequency.

See freqafrq() for a description of the API.

freqawav()

```
int freqawav (
              SPX_ARGS  )
```

Convert frequency to air wavelength (vector).

freqawav() converts frequency to air wavelength.

See freqafrq() for a description of the API.

awavfreq()

```
int awavfreq (
              SPX_ARGS  )
```

Convert air wavelength to frequency (vector).

awavfreq() converts air wavelength to frequency.

See freqafrq() for a description of the API.

waveawav()

```
int waveawav (
              SPX_ARGS  )
```

Convert vacuum wavelength to air wavelength (vector).

waveawav() converts vacuum wavelength to air wavelength.

See freqafrq() for a description of the API.

awavwave()

```
int awavwave (
              SPX_ARGS  )
```

Convert air wavelength to vacuum wavelength (vector).

awavwave() converts air wavelength to vacuum wavelength.

See freqafrq() for a description of the API.

velobeta()

```
int velobeta (
              SPX_ARGS  )
```

Convert relativistic velocity to relativistic beta (vector).

velobeta() converts relativistic velocity to relativistic beta.

See freqafrq() for a description of the API.

betavelo()

```
int betavelo (
              SPX_ARGS  )
```

Convert relativistic beta to relativistic velocity (vector).

betavelo() converts relativistic beta to relativistic velocity.

See freqafrq() for a description of the API.

freqvelo()

```
int freqvelo (
              SPX_ARGS  )
```

Convert frequency to relativistic velocity (vector).

freqvelo() converts frequency to relativistic velocity.

Parameters

in	*param*	Rest frequency [Hz].
in	*nspec*	Vector length.
in	*instep,outstep*	Vector strides.
in	*inspec*	Input spectral variables, in SI units.
out	*outspec*	Output spectral variables, in SI units.
out	*stat*	Status return value for each vector element: • 0: Success. • 1: Invalid value of inspec.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.
- 4: One or more of the inspec coordinates were invalid, as indicated by the stat vector.

velofreq()

```
int velofreq (
              SPX_ARGS  )
```

Convert relativistic velocity to frequency (vector).

velofreq() converts relativistic velocity to frequency.

See freqvelo() for a description of the API.

freqvrad()

```
int freqvrad (
              SPX_ARGS  )
```

Convert frequency to radio velocity (vector).

freqvrad() converts frequency to radio velocity.

See freqvelo() for a description of the API.

vradfreq()

```
int vradfreq (
              SPX_ARGS  )
```

Convert radio velocity to frequency (vector).

vradfreq() converts radio velocity to frequency.

See freqvelo() for a description of the API.

wavevelo()

```
int wavevelo (
            SPX_ARGS  )
```

Conversions between wavelength and velocity types (vector).

wavevelo() converts vacuum wavelength to relativistic velocity.

Parameters

in	*param*	Rest wavelength in vacuo [m].
in	*nspec*	Vector length.
in	*instep,outstep*	Vector strides.
in	*inspec*	Input spectral variables, in SI units.
out	*outspec*	Output spectral variables, in SI units.
out	*stat*	Status return value for each vector element: • 0: Success. • 1: Invalid value of inspec.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.
- 4: One or more of the inspec coordinates were invalid, as indicated by the stat vector.

velowave()

```
int velowave (
            SPX_ARGS  )
```

Convert relativistic velocity to vacuum wavelength (vector).

velowave() converts relativistic velocity to vacuum wavelength.

See freqvelo() for a description of the API.

awavvelo()

```
int awavvelo (
            SPX_ARGS  )
```

Convert air wavelength to relativistic velocity (vector).

awavvelo() converts air wavelength to relativistic velocity.

See freqvelo() for a description of the API.

veloawav()

```
int veloawav (
              SPX_ARGS  )
```

Convert relativistic velocity to air wavelength (vector).

veloawav() converts relativistic velocity to air wavelength.

See freqvelo() for a description of the API.

wavevopt()

```
int wavevopt (
              SPX_ARGS  )
```

Convert vacuum wavelength to optical velocity (vector).

wavevopt() converts vacuum wavelength to optical velocity.

See freqvelo() for a description of the API.

voptwave()

```
int voptwave (
              SPX_ARGS  )
```

Convert optical velocity to vacuum wavelength (vector).

voptwave() converts optical velocity to vacuum wavelength.

See freqvelo() for a description of the API.

wavezopt()

```
int wavezopt (
              SPX_ARGS  )
```

Convert vacuum wavelength to redshift (vector).

wavevopt() converts vacuum wavelength to redshift.

See freqvelo() for a description of the API.

zoptwave()

```
int zoptwave (
              SPX_ARGS  )
```

Convert redshift to vacuum wavelength (vector).

zoptwave() converts redshift to vacuum wavelength.

See freqvelo() for a description of the API.

00023 *===========================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the spx routines
00031 * ---------------------------
00032 * Routines in this suite implement the spectral coordinate systems recognized
00033 * by the FITS World Coordinate System (WCS) standard, as described in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 =
00038 =   "Representations of spectral coordinates in FITS",
00039 =   Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00040 =   2006, A&A, 446, 747 (WCS Paper III)
00041 *
00042 * specx() is a scalar routine that, given one spectral variable (e.g.
00043 * frequency), computes all the others (e.g. wavelength, velocity, etc.) plus
00044 * the required derivatives of each with respect to the others.  The results
00045 * are returned in the spxprm struct.
00046 *
00047 * spxperr() prints the error message(s) (if any) stored in a spxprm struct.
00048 *
00049 * The remaining routines are all vector conversions from one spectral
00050 * variable to another.  The API of these functions only differ in whether the
00051 * rest frequency or wavelength need be supplied.
00052 *
00053 * Non-linear:
00054 *    - freqwave()    frequency              ->  vacuum wavelength
00055 *    - wavefreq()    vacuum wavelength      ->  frequency
00056 *
00057 *    - freqawav()    frequency              ->  air wavelength
00058 *    - awavfreq()    air wavelength         ->  frequency
00059 *
00060 *    - freqvelo()    frequency              ->  relativistic velocity
00061 *    - velofreq()    relativistic velocity  ->  frequency
00062 *
00063 *    - waveawav()    vacuum wavelength      ->  air wavelength
00064 *    - awavwave()    air wavelength         ->  vacuum wavelength
00065 *
00066 *    - wavevelo()    vacuum wavelength      ->  relativistic velocity
00067 *    - velowave()    relativistic velocity  ->  vacuum wavelength
00068 *
00069 *    - awavvelo()    air wavelength         ->  relativistic velocity
00070 *    - veloawav()    relativistic velocity  ->  air wavelength
```

```
00071 *
00072 * Linear:
00073 *   - freqafrq()    frequency              ->  angular frequency
00074 *   - afrqfreq()    angular frequency      ->  frequency
00075 *
00076 *   - freqener()    frequency              ->  energy
00077 *   - enerfreq()    energy                 ->  frequency
00078 *
00079 *   - freqwavn()    frequency              ->  wave number
00080 *   - wavnfreq()    wave number            ->  frequency
00081 *
00082 *   - freqvrad()    frequency              ->  radio velocity
00083 *   - vradfreq()    radio velocity         ->  frequency
00084 *
00085 *   - wavevopt()    vacuum wavelength      ->  optical velocity
00086 *   - voptwave()    optical velocity       ->  vacuum wavelength
00087 *
00088 *   - wavezopt()    vacuum wavelength      ->  redshift
00089 *   - zoptwave()    redshift               ->  vacuum wavelength
00090 *
00091 *   - velobeta()    relativistic velocity  ->  beta (= v/c)
00092 *   - betavelo()    beta (= v/c)           ->  relativistic velocity
00093 *
00094 * These are the workhorse routines, to be used for fast transformations.
00095 * Conversions may be done "in place" by calling the routine with the output
00096 * vector set to the input.
00097 *
00098 * Air-to-vacuum wavelength conversion:
00099 * ------------------------------------
00100 * The air-to-vacuum wavelength conversion in early drafts of WCS Paper III
00101 * cites Cox (ed., 2000, Allen's Astrophysical Quantities, AIP Press,
00102 * Springer-Verlag, New York), which itself derives from Edlén (1953, Journal
00103 * of the Optical Society of America, 43, 339).  This is the IAU standard,
00104 * adopted in 1957 and again in 1991.  No more recent IAU resolution replaces
00105 * this relation, and it is the one used by WCSLIB.
00106 *
00107 * However, the Cox relation was replaced in later drafts of Paper III, and as
00108 * eventually published, by the IUGG relation (1999, International Union of
00109 * Geodesy and Geophysics, comptes rendus of the 22nd General Assembly,
00110 * Birmingham UK, p111).  There is a nearly constant ratio between the two,
00111 * with IUGG/Cox = 1.000015 over most of the range between 200nm and 10,000nm.
00112 *
00113 * The IUGG relation itself is derived from the work of Ciddor (1996, Applied
00114 * Optics, 35, 1566), which is used directly by the Sloan Digital Sky Survey.
00115 * It agrees closely with Cox; longwards of 2500nm, the ratio Ciddor/Cox is
00116 * fixed at 1.000000021, decreasing only slightly, to 1.000000018, at 1000nm.
00117 *
00118 * The Cox, IUGG, and Ciddor relations all accurately provide the wavelength
00119 * dependence of the air-to-vacuum wavelength conversion.  However, for full
00120 * accuracy, the atmospheric temperature, pressure, and partial pressure of
00121 * water vapour must be taken into account.  These will determine a small,
00122 * wavelength-independent scale factor and offset, which is not considered by
00123 * WCS Paper III.
00124 *
00125 * WCS Paper III is also silent on the question of the range of validity of the
00126 * air-to-vacuum wavelength conversion.  Cox's relation would appear to be
00127 * valid in the range 200nm to 10,000nm.  Both the Cox and the Ciddor relations
00128 * have singularities below 200nm, with Cox's at 156nm and 83nm.  WCSLIB checks
00129 * neither the range of validity, nor for these singularities.
00130 *
00131 * Argument checking:
00132 * ------------------
00133 * The input spectral values are only checked for values that would result
00134 * in floating point exceptions.  In particular, negative frequencies and
00135 * wavelengths are allowed, as are velocities greater than the speed of
00136 * light.  The same is true for the spectral parameters - rest frequency and
00137 * wavelength.
00138 *
00139 * Accuracy:
00140 * ---------
00141 * No warranty is given for the accuracy of these routines (refer to the
00142 * copyright notice); intending users must satisfy for themselves their
00143 * adequacy for the intended purpose.  However, closure effectively to within
00144 * double precision rounding error was demonstrated by test routine tspec.c
00145 * which accompanies this software.
00146 *
00147 *
00148 * specx() - Spectral cross conversions (scalar)
00149 * ---------------------------------------------
00150 * Given one spectral variable specx() computes all the others, plus the
00151 * required derivatives of each with respect to the others.
00152 *
00153 * Given:
00154 *   type      const char*
00155 *                       The type of spectral variable given by spec, FREQ,
00156 *                       AFRQ, ENER, WAVN, VRAD, WAVE, VOPT, ZOPT, AWAV, VELO,
00157 *                       or BETA (case sensitive).
```

```
00158 *
00159 *   spec      double    The spectral variable given, in SI units.
00160 *
00161 *   restfrq,
00162 *   restwav   double    Rest frequency [Hz] or rest wavelength in vacuo [m],
00163 *                       only one of which need be given.  The other should be
00164 *                       set to zero.  If both are zero, only a subset of the
00165 *                       spectral variables can be computed, the remainder are
00166 *                       set to zero.  Specifically, given one of FREQ, AFRQ,
00167 *                       ENER, WAVN, WAVE, or AWAV the others can be computed
00168 *                       without knowledge of the rest frequency.  Likewise,
00169 *                       VRAD, VOPT, ZOPT, VELO, and BETA.
00170 *
00171 * Given and returned:
00172 *   specs     struct spxprm*
00173 *                       Data structure containing all spectral variables and
00174 *                       their derivatives, in SI units.
00175 *
00176 * Function return value:
00177 *             int       Status return value:
00178 *                         0: Success.
00179 *                         1: Null spxprm pointer passed.
00180 *                         2: Invalid spectral parameters.
00181 *                         3: Invalid spectral variable.
00182 *
00183 *                       For returns > 1, a detailed error message is set in
00184 *                       spxprm::err if enabled, see wcserr_enable().
00185 *
00186 * freqafrq(), afrqfreq(), freqener(), enerfreq(), freqwavn(), wavnfreq(),
00187 * freqwave(), wavefreq(), freqawav(), awavfreq(), waveawav(), awavwave(),
00188 * velobeta(), and betavelo() implement vector conversions between wave-like
00189 * or velocity-like spectral types (i.e. conversions that do not need the rest
00190 * frequency or wavelength).  They all have the same API.
00191 *
00192 *
00193 * spxperr() - Print error messages from a spxprm struct
00194 * -----------------------------------------------------
00195 * spxperr() prints the error message(s) (if any) stored in a spxprm struct.
00196 * If there are no errors then nothing is printed.  It uses wcserr_prt(), q.v.
00197 *
00198 * Given:
00199 *   spx       const struct spxprm*
00200 *                       Spectral variables and their derivatives.
00201 *
00202 *   prefix    const char *
00203 *                       If non-NULL, each output line will be prefixed with
00204 *                       this string.
00205 *
00206 * Function return value:
00207 *             int       Status return value:
00208 *                         0: Success.
00209 *                         1: Null spxprm pointer passed.
00210 *
00211 *
00212 * freqafrq() - Convert frequency to angular frequency (vector)
00213 * ------------------------------------------------------------
00214 * freqafrq() converts frequency to angular frequency.
00215 *
00216 * Given:
00217 *   param     double    Ignored.
00218 *
00219 *   nspec     int       Vector length.
00220 *
00221 *   instep,
00222 *   outstep   int       Vector strides.
00223 *
00224 *   inspec    const double[]
00225 *                       Input spectral variables, in SI units.
00226 *
00227 * Returned:
00228 *   outspec   double[]  Output spectral variables, in SI units.
00229 *
00230 *   stat      int[]     Status return value for each vector element:
00231 *                         0: Success.
00232 *                         1: Invalid value of inspec.
00233 *
00234 * Function return value:
00235 *             int       Status return value:
00236 *                         0: Success.
00237 *                         2: Invalid spectral parameters.
00238 *                         4: One or more of the inspec coordinates were
00239 *                            invalid, as indicated by the stat vector.
00240 *
00241 *
00242 * freqvelo(), velofreq(), freqvrad(), and vradfreq() implement vector
00243 * conversions between frequency and velocity spectral types.  They all have
00244 * the same API.
```

```
00245 *
00246 *
00247 * freqvelo() - Convert frequency to relativistic velocity (vector)
00248 * ---------------------------------------------------------------
00249 * freqvelo() converts frequency to relativistic velocity.
00250 *
00251 * Given:
00252 *   param     double    Rest frequency [Hz].
00253 *
00254 *   nspec     int       Vector length.
00255 *
00256 *   instep,
00257 *   outstep   int       Vector strides.
00258 *
00259 *   inspec    const double[]
00260 *                       Input spectral variables, in SI units.
00261 *
00262 * Returned:
00263 *   outspec   double[]  Output spectral variables, in SI units.
00264 *
00265 *   stat      int[]     Status return value for each vector element:
00266 *                         0: Success.
00267 *                         1: Invalid value of inspec.
00268 *
00269 * Function return value:
00270 *             int       Status return value:
00271 *                         0: Success.
00272 *                         2: Invalid spectral parameters.
00273 *                         4: One or more of the inspec coordinates were
00274 *                            invalid, as indicated by the stat vector.
00275 *
00276 *
00277 * wavevelo(), velowave(), awavvelo(), veloawav(), wavevopt(), voptwave(),
00278 * wavezopt(), and zoptwave() implement vector conversions between wavelength
00279 * and velocity spectral types.  They all have the same API.
00280 *
00281 *
00282 * wavevelo() - Conversions between wavelength and velocity types (vector)
00283 * -----------------------------------------------------------------------
00284 * wavevelo() converts vacuum wavelength to relativistic velocity.
00285 *
00286 * Given:
00287 *   param     double    Rest wavelength in vacuo [m].
00288 *
00289 *   nspec     int       Vector length.
00290 *
00291 *   instep,
00292 *   outstep   int       Vector strides.
00293 *
00294 *   inspec    const double[]
00295 *                       Input spectral variables, in SI units.
00296 *
00297 * Returned:
00298 *   outspec   double[]  Output spectral variables, in SI units.
00299 *
00300 *   stat      int[]     Status return value for each vector element:
00301 *                         0: Success.
00302 *                         1: Invalid value of inspec.
00303 *
00304 * Function return value:
00305 *             int       Status return value:
00306 *                         0: Success.
00307 *                         2: Invalid spectral parameters.
00308 *                         4: One or more of the inspec coordinates were
00309 *                            invalid, as indicated by the stat vector.
00310 *
00311 *
00312 * spxprm struct - Spectral variables and their derivatives
00313 * --------------------------------------------------------
00314 * The spxprm struct contains the value of all spectral variables and their
00315 * derivatives.   It is used solely by specx() which constructs it from
00316 * information provided via its function arguments.
00317 *
00318 * This struct should be considered read-only, no members need ever be set nor
00319 * should ever be modified by the user.
00320 *
00321 *   double restfrq
00322 *     (Returned) Rest frequency [Hz].
00323 *
00324 *   double restwav
00325 *     (Returned) Rest wavelength [m].
00326 *
00327 *   int wavetype
00328 *     (Returned) True if wave types have been computed, and ...
00329 *
00330 *   int velotype
00331 *     (Returned) ... true if velocity types have been computed; types are
```

```
00332 *     defined below.
00333 *
00334 *     If one or other of spxprm::restfrq and spxprm::restwav is given
00335 *     (non-zero) then all spectral variables may be computed.  If both are
00336 *     given, restfrq is used.  If restfrq and restwav are both zero, only wave
00337 *     characteristic xor velocity type spectral variables may be computed
00338 *     depending on the variable given.   These flags indicate what is
00339 *     available.
00340 *
00341 *   double freq
00342 *     (Returned) Frequency [Hz] (wavetype).
00343 *
00344 *   double afrq
00345 *     (Returned) Angular frequency [rad/s] (wavetype).
00346 *
00347 *   double ener
00348 *     (Returned) Photon energy [J] (wavetype).
00349 *
00350 *   double wavn
00351 *     (Returned) Wave number [/m] (wavetype).
00352 *
00353 *   double vrad
00354 *     (Returned) Radio velocity [m/s] (velotype).
00355 *
00356 *   double wave
00357 *     (Returned) Vacuum wavelength [m] (wavetype).
00358 *
00359 *   double vopt
00360 *     (Returned) Optical velocity [m/s] (velotype).
00361 *
00362 *   double zopt
00363 *     (Returned) Redshift [dimensionless] (velotype).
00364 *
00365 *   double awav
00366 *     (Returned) Air wavelength [m] (wavetype).
00367 *
00368 *   double velo
00369 *     (Returned) Relativistic velocity [m/s] (velotype).
00370 *
00371 *   double beta
00372 *     (Returned) Relativistic beta [dimensionless] (velotype).
00373 *
00374 *   double dfreqafrq
00375 *     (Returned) Derivative of frequency with respect to angular frequency
00376 *     [/rad] (constant, = 1 / 2*pi), and ...
00377 *   double dafrqfreq
00378 *     (Returned) ... vice versa [rad] (constant, = 2*pi, always available).
00379 *
00380 *   double dfreqener
00381 *     (Returned) Derivative of frequency with respect to photon energy
00382 *     [/J/s] (constant, = 1/h), and ...
00383 *   double denerfreq
00384 *     (Returned) ... vice versa [Js] (constant, = h, Planck's constant,
00385 *     always available).
00386 *
00387 *   double dfreqwavn
00388 *     (Returned) Derivative of frequency with respect to wave number [m/s]
00389 *     (constant, = c, the speed of light in vacuo), and ...
00390 *   double dwavnfreq
00391 *     (Returned) ... vice versa [s/m] (constant, = 1/c, always available).
00392 *
00393 *   double dfreqvrad
00394 *     (Returned) Derivative of frequency with respect to radio velocity [/m],
00395 *     and ...
00396 *   double dvradfreq
00397 *     (Returned) ... vice versa [m] (wavetype && velotype).
00398 *
00399 *   double dfreqwave
00400 *     (Returned) Derivative of frequency with respect to vacuum wavelength
00401 *     [/m/s], and ...
00402 *   double dwavefreq
00403 *     (Returned) ... vice versa [m s] (wavetype).
00404 *
00405 *   double dfreqawav
00406 *     (Returned) Derivative of frequency with respect to air wavelength,
00407 *     [/m/s], and ...
00408 *   double dawavfreq
00409 *     (Returned) ... vice versa [m s] (wavetype).
00410 *
00411 *   double dfreqvelo
00412 *     (Returned) Derivative of frequency with respect to relativistic
00413 *     velocity [/m], and ...
00414 *   double dvelofreq
00415 *     (Returned) ... vice versa [m] (wavetype && velotype).
00416 *
00417 *   double dwavevopt
00418 *     (Returned) Derivative of vacuum wavelength with respect to optical
```

```
00419 *     velocity [s], and ...
00420 *   double dvoptwave
00421 *     (Returned) ... vice versa [/s] (wavetype && velotype).
00422 *
00423 *   double dwavezopt
00424 *     (Returned) Derivative of vacuum wavelength with respect to redshift [m],
00425 *     and ...
00426 *   double dzoptwave
00427 *     (Returned) ... vice versa [/m] (wavetype && velotype).
00428 *
00429 *   double dwaveawav
00430 *     (Returned) Derivative of vacuum wavelength with respect to air
00431 *     wavelength [dimensionless], and ...
00432 *   double dawavwave
00433 *     (Returned) ... vice versa [dimensionless] (wavetype).
00434 *
00435 *   double dwavevelo
00436 *     (Returned) Derivative of vacuum wavelength with respect to relativistic
00437 *     velocity [s], and ...
00438 *   double dvelowave
00439 *     (Returned) ... vice versa [/s] (wavetype && velotype).
00440 *
00441 *   double dawavvelo
00442 *     (Returned) Derivative of air wavelength with respect to relativistic
00443 *     velocity [s], and ...
00444 *   double dveloawav
00445 *     (Returned) ... vice versa [/s] (wavetype && velotype).
00446 *
00447 *   double dvelobeta
00448 *     (Returned) Derivative of relativistic velocity with respect to
00449 *     relativistic beta [m/s] (constant, = c, the speed of light in vacuo),
00450 *     and ...
00451 *   double dbetavelo
00452 *     (Returned) ... vice versa [s/m] (constant, = 1/c, always available).
00453 *
00454 *   struct wcserr *err
00455 *     (Returned) If enabled, when an error status is returned, this struct
00456 *     contains detailed information about the error, see wcserr_enable().

6.21 tab.h File Reference

Data Structures

- struct tabprm

  Tabular transformation parameters.

Macros

- #define TABLEN (sizeof(struct tabprm)/sizeof(int))

  Size of the tabprm struct in int units.
- #define tabini_errmsg tab_errmsg

  Deprecated.
- #define tabcpy_errmsg tab_errmsg

  Deprecated.
- #define tabfree_errmsg tab_errmsg

  Deprecated.
- #define tabprt_errmsg tab_errmsg

  Deprecated.
- #define tabset_errmsg tab_errmsg

  Deprecated.
- #define tabx2s_errmsg tab_errmsg

  Deprecated.
- #define tabs2x_errmsg tab_errmsg

  Deprecated.

Enumerations

- enum tab_errmsg_enum {
  TABERR_SUCCESS = 0 , TABERR_NULL_POINTER = 1 , TABERR_MEMORY = 2 , TABERR_BAD_PARAMS = 3 ,
  TABERR_BAD_X = 4 , TABERR_BAD_WORLD = 5 }

Functions

- int tabini (int alloc, int M, const int K[ ], struct tabprm *tab)

  Default constructor for the tabprm struct.
- int tabmem (struct tabprm *tab)

  Acquire tabular memory.
- int tabcpy (int alloc, const struct tabprm *tabsrc, struct tabprm *tabdst)

  Copy routine for the tabprm struct.
- int tabcmp (int cmp, double tol, const struct tabprm *tab1, const struct tabprm *tab2, int *equal)

  Compare two tabprm structs for equality.
- int tabfree (struct tabprm *tab)

  Destructor for the tabprm struct.
- int tabsize (const struct tabprm *tab, int size[2])

  Compute the size of a tabprm struct.
- int tabprt (const struct tabprm *tab)

  Print routine for the tabprm struct.

- int tabperr (const struct tabprm *tab, const char *prefix)

  Print error messages from a tabprm struct.
- int tabset (struct tabprm *tab)

  Setup routine for the tabprm struct.
- int tabx2s (struct tabprm *tab, int ncoord, int nelem, const double x[ ], double world[ ], int stat[ ])

  Pixel-to-world transformation.
- int tabs2x (struct tabprm *tab, int ncoord, int nelem, const double world[ ], double x[ ], int stat[ ])

  World-to-pixel transformation.

Variables

- const char * tab_errmsg [ ]

  Status return messages.

6.21.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with tabular coordinates, i.e. coordinates that are defined via a lookup table, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)
```

These routines define methods to be used for computing tabular world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa. They are based on the tabprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

tabini(), tabmem(), tabcpy(), and tabfree() are provided to manage the tabprm struct, tabsize() computes its total size including allocated memory, and tabprt() prints its contents.

tabperr() prints the error message(s) (if any) stored in a tabprm struct.

A setup routine, tabset(), computes intermediate values in the tabprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by tabset() but it need not be called explicitly - refer to the explanation of tabprm::flag.

tabx2s() and tabs2x() implement the WCS tabular coordinate transformations.

Accuracy:
No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine ttab.c which accompanies this software.

6.21.2 Macro Definition Documentation

TABLEN

```
#define TABLEN (sizeof(struct tabprm)/sizeof(int))
```

Size of the tabprm struct in *int* units.

Size of the tabprm struct in *int* units, used by the Fortran wrappers.

tabini_errmsg

```
#define tabini_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabcpy_errmsg

```
#define tabcpy_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabfree_errmsg

```
#define tabfree_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabprt_errmsg

```
#define tabprt_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabset_errmsg

```
#define tabset_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabx2s_errmsg

```
#define tabx2s_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabs2x_errmsg

```
#define tabs2x_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

6.21.3 Enumeration Type Documentation

tab_errmsg_enum

```
enum tab_errmsg_enum
```

Enumerator

TABERR_SUCCESS	
TABERR_NULL_POINTER	
TABERR_MEMORY	
TABERR_BAD_PARAMS	
TABERR_BAD_X	
TABERR_BAD_WORLD	

6.21.4 Function Documentation

tabini()

```
int tabini (
            int alloc,
            int M,
            const int K[],
            struct tabprm * tab )
```

Default constructor for the tabprm struct.

tabini() allocates memory for arrays in a tabprm struct and sets all members of the struct to default values.

PLEASE NOTE: every tabprm struct should be initialized by **tabini**(), possibly repeatedly. On the first invokation, and only the first invokation, the flag member of the tabprm struct must be set to -1 to initialize memory management, regardless of whether **tabini**() will actually be used to allocate memory.

Parameters

in	*alloc*	If true, allocate memory unconditionally for arrays in the tabprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	*M*	The number of tabular coordinate axes.
in	*K*	Vector of length M whose elements $(K_1, K_2, ...K_M)$ record the lengths of the axes of the coordinate array and of each indexing vector. M and K[] are used to determine the length of the various tabprm arrays and therefore the amount of memory to allocate for them. Their values are copied into the tabprm struct. It is permissible to set K (i.e. the address of the array) to zero which has the same effect as setting each element of K[] to zero. In this case no memory will be allocated for the index vectors or coordinate array in the tabprm struct. These together with the K vector must be set separately before calling tabset().
in,out	*tab*	Tabular transformation parameters. Note that, in order to initialize memory management tabprm::flag should be set to -1 when tab is initialized for the first time (memory leaks may result if it had already been initialized).

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid tabular parameters.

For returns $>$ 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabmem()

```
int tabmem (
            struct tabprm * tab )
```

Acquire tabular memory.

tabmem() takes control of memory allocated by the user for arrays in the tabprm struct.

Parameters

in,out	*tab*	Tabular transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabcpy()

```
int tabcpy (
            int alloc,
            const struct tabprm * tabsrc,
            struct tabprm * tabdst )
```

Copy routine for the tabprm struct.

tabcpy() does a deep copy of one tabprm struct to another, using tabini() to allocate memory for its arrays if required. Only the "information to be provided" part of the struct is copied; a call to tabset() is required to set up the remainder.

Parameters

in	*alloc*	If true, allocate memory unconditionally for arrays in the tabprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	*tabsrc*	Struct to copy from.
in,out	*tabdst*	Struct to copy to. tabprm::flag should be set to -1 if tabdst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in tabprm::err (associated with tabdst) if enabled, see wcserr_enable().

tabcmp()

```
int tabcmp (
            int cmp,
            double tol,
            const struct tabprm * tab1,
            const struct tabprm * tab2,
            int * equal )
```

Compare two tabprm structs for equality.

tabcmp() compares two tabprm structs for equality.

Parameters

in	*cmp*	A bit field controlling the strictness of the comparison. At present, this value must always be 0, indicating a strict comparison. In the future, other options may be added.
in	*tol*	Tolerance for comparison of floating-point values. For example, for tol == 1e-6, all floating-point values in the structs must be equal to the first 6 decimal places. A value of 0 implies exact equality.
in	*tab1*	The first tabprm struct to compare.
in	*tab2*	The second tabprm struct to compare.
out	*equal*	Non-zero when the given structs are equal.

Returns

Status return value:

- 0: Success.
- 1: Null pointer passed.

tabfree()

```
int tabfree (
            struct tabprm * tab )
```

Destructor for the tabprm struct.

tabfree() frees memory allocated for the tabprm arrays by tabini(). tabini() records the memory it allocates and **tabfree**() will only attempt to free this.

PLEASE NOTE: tabfree() must not be invoked on a tabprm struct that was not initialized by tabini().

Parameters

out	*tab*	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.

tabsize()

```
int tabsize (
            const struct tabprm * tab,
            int size[2] )
```

Compute the size of a tabprm struct.

tabsize() computes the full size of a tabprm struct, including allocated memory.

Parameters

in	*tab*	Tabular transformation parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct tabprm). The second element is the total allocated size, in bytes, assuming that the allocation was done by tabini(). This figure includes memory allocated for the constituent struct, tabprm::err. It is not an error for the struct not to have been set up via tabset(), which normally results in additional memory allocation.

Returns

Status return value:

- 0: Success.

tabprt()

```
int tabprt (
              const struct tabprm * tab )
```

Print routine for the tabprm struct.

tabprt() prints the contents of a tabprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*tab*	Tabular transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.

tabperr()

```
int tabperr (
              const struct tabprm * tab,
              const char * prefix )
```

Print error messages from a tabprm struct.

tabperr() prints the error message(s) (if any) stored in a tabprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*tab*	Tabular transformation parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.

tabset()

```
int tabset (
            struct tabprm * tab )
```

Setup routine for the tabprm struct.

tabset() allocates memory for work arrays in the tabprm struct and sets up the struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by tabx2s() and tabs2x() if tabprm::flag is anything other than a predefined magic value.

Parameters

in,out	*tab*	Tabular transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 3: Invalid tabular parameters.

For returns $>$ 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabx2s()

```
int tabx2s (
            struct tabprm * tab,
            int ncoord,
            int nelem,
            const double x[],
            double world[],
            int stat[] )
```

Pixel-to-world transformation.

tabx2s() transforms intermediate world coordinates to world coordinates using coordinate lookup.

Parameters

in,out	*tab*	Tabular transformation parameters.
in	*ncoord,nelem*	The number of coordinates, each of vector length nelem.
in	*x*	Array of intermediate world coordinates, SI units.
out	*world*	Array of world coordinates, in SI units.
out	*stat*	Status return value status for each coordinate: • 0: Success. • 1: Invalid intermediate world coordinate.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 3: Invalid tabular parameters.
- 4: One or more of the x coordinates were invalid, as indicated by the stat vector.

For returns $>$ 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabs2x()

```
int tabs2x (
              struct tabprm * tab,
              int ncoord,
              int nelem,
              const double world[],
              double x[],
              int stat[] )
```

World-to-pixel transformation.

tabs2x() transforms world coordinates to intermediate world coordinates.

Parameters

in,out	*tab*	Tabular transformation parameters.
in	*ncoord,nelem*	The number of coordinates, each of vector length nelem.
in	*world*	Array of world coordinates, in SI units.
out	*x*	Array of intermediate world coordinates, SI units.
out	*stat*	Status return value status for each vector element: • 0: Success. • 1: Invalid world coordinate.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 3: Invalid tabular parameters.
- 5: One or more of the world coordinates were invalid, as indicated by the stat vector.

For returns $>$ 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

6.21.5 Variable Documentation

tab_errmsg

```
const char * tab_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

6.22 tab.h

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the tab routines
00031 * ---------------------------
00032 * Routines in this suite implement the part of the FITS World Coordinate
00033 * System (WCS) standard that deals with tabular coordinates, i.e. coordinates
00034 * that are defined via a lookup table, as described in
00035 *
00036 =   "Representations of world coordinates in FITS",
00037 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00038 =
00039 =   "Representations of spectral coordinates in FITS",
00040 =   Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00041 =   2006, A&A, 446, 747 (WCS Paper III)
00042 *
00043 * These routines define methods to be used for computing tabular world
00044 * coordinates from intermediate world coordinates (a linear transformation
00045 * of image pixel coordinates), and vice versa.  They are based on the tabprm
00046 * struct which contains all information needed for the computations.  The
00047 * struct contains some members that must be set by the user, and others that
00048 * are maintained by these routines, somewhat like a C++ class but with no
00049 * encapsulation.
00050 *
00051 * tabini(), tabmem(), tabcpy(), and tabfree() are provided to manage the
00052 * tabprm struct, tabsize() computes its total size including allocated memory,
00053 * and tabprt() prints its contents.
00054 *
00055 * tabperr() prints the error message(s) (if any) stored in a tabprm struct.
00056 *
00057 * A setup routine, tabset(), computes intermediate values in the tabprm struct
00058 * from parameters in it that were supplied by the user.  The struct always
00059 * needs to be set up by tabset() but it need not be called explicitly - refer
00060 * to the explanation of tabprm::flag.
00061 *
00062 * tabx2s() and tabs2x() implement the WCS tabular coordinate transformations.
00063 *
00064 * Accuracy:
00065 * ---------
00066 * No warranty is given for the accuracy of these routines (refer to the
00067 * copyright notice); intending users must satisfy for themselves their
00068 * adequacy for the intended purpose.  However, closure effectively to within
00069 * double precision rounding error was demonstrated by test routine ttab.c
00070 * which accompanies this software.
00071 *
00072 *
00073 * tabini() - Default constructor for the tabprm struct
00074 * ----------------------------------------------------
```

```
00075 * tabini() allocates memory for arrays in a tabprm struct and sets all members
00076 * of the struct to default values.
00077 *
00078 * PLEASE NOTE: every tabprm struct should be initialized by tabini(), possibly
00079 * repeatedly.  On the first invokation, and only the first invokation, the
00080 * flag member of the tabprm struct must be set to -1 to initialize memory
00081 * management, regardless of whether tabini() will actually be used to allocate
00082 * memory.
00083 *
00084 * Given:
00085 *   alloc     int       If true, allocate memory unconditionally for arrays in
00086 *                       the tabprm struct.
00087 *
00088 *                       If false, it is assumed that pointers to these arrays
00089 *                       have been set by the user except if they are null
00090 *                       pointers in which case memory will be allocated for
00091 *                       them regardless.  (In other words, setting alloc true
00092 *                       saves having to initalize these pointers to zero.)
00093 *
00094 *   M         int       The number of tabular coordinate axes.
00095 *
00096 *   K         const int[]
00097 *                       Vector of length M whose elements (K_1, K_2,... K_M)
00098 *                       record the lengths of the axes of the coordinate array
00099 *                       and of each indexing vector.  M and K[] are used to
00100 *                       determine the length of the various tabprm arrays and
00101 *                       therefore the amount of memory to allocate for them.
00102 *                       Their values are copied into the tabprm struct.
00103 *
00104 *                       It is permissible to set K (i.e. the address of the
00105 *                       array) to zero which has the same effect as setting
00106 *                       each element of K[] to zero.  In this case no memory
00107 *                       will be allocated for the index vectors or coordinate
00108 *                       array in the tabprm struct.  These together with the
00109 *                       K vector must be set separately before calling
00110 *                       tabset().
00111 *
00112 * Given and returned:
00113 *   tab       struct tabprm*
00114 *                       Tabular transformation parameters.  Note that, in
00115 *                       order to initialize memory management tabprm::flag
00116 *                       should be set to -1 when tab is initialized for the
00117 *                       first time (memory leaks may result if it had already
00118 *                       been initialized).
00119 *
00120 * Function return value:
00121 *             int       Status return value:
00122 *                         0: Success.
00123 *                         1: Null tabprm pointer passed.
00124 *                         2: Memory allocation failed.
00125 *                         3: Invalid tabular parameters.
00126 *
00127 *                       For returns > 1, a detailed error message is set in
00128 *                       tabprm::err if enabled, see wcserr_enable().
00129 *
00130 *
00131 * tabmem() - Acquire tabular memory
00132 * ---------------------------------
00133 * tabmem() takes control of memory allocated by the user for arrays in the
00134 * tabprm struct.
00135 *
00136 * Given and returned:
00137 *   tab       struct tabprm*
00138 *                       Tabular transformation parameters.
00139 *
00140 * Function return value:
00141 *             int       Status return value:
00142 *                         0: Success.
00143 *                         1: Null tabprm pointer passed.
00144 *                         2: Memory allocation failed.
00145 *
00146 *                       For returns > 1, a detailed error message is set in
00147 *                       tabprm::err if enabled, see wcserr_enable().
00148 *
00149 *
00150 * tabcpy() - Copy routine for the tabprm struct
00151 * ---------------------------------------------
00152 * tabcpy() does a deep copy of one tabprm struct to another, using tabini() to
00153 * allocate memory for its arrays if required.  Only the "information to be
00154 * provided" part of the struct is copied; a call to tabset() is required to
00155 * set up the remainder.
00156 *
00157 * Given:
00158 *   alloc     int       If true, allocate memory unconditionally for arrays in
00159 *                       the tabprm struct.
00160 *
00161 *                       If false, it is assumed that pointers to these arrays
```

```
00162 *                       have been set by the user except if they are null
00163 *                       pointers in which case memory will be allocated for
00164 *                       them regardless.  (In other words, setting alloc true
00165 *                       saves having to initalize these pointers to zero.)
00166 *
00167 *   tabsrc    const struct tabprm*
00168 *                       Struct to copy from.
00169 *
00170 * Given and returned:
00171 *   tabdst    struct tabprm*
00172 *                       Struct to copy to.  tabprm::flag should be set to -1
00173 *                       if tabdst was not previously initialized (memory leaks
00174 *                       may result if it was previously initialized).
00175 *
00176 * Function return value:
00177 *             int       Status return value:
00178 *                         0: Success.
00179 *                         1: Null tabprm pointer passed.
00180 *                         2: Memory allocation failed.
00181 *
00182 *                       For returns > 1, a detailed error message is set in
00183 *                       tabprm::err (associated with tabdst) if enabled, see
00184 *                       wcserr_enable().
00185 *
00186 *
00187 * tabcmp() - Compare two tabprm structs for equality
00188 * --------------------------------------------------
00189 * tabcmp() compares two tabprm structs for equality.
00190 *
00191 * Given:
00192 *   cmp       int       A bit field controlling the strictness of the
00193 *                       comparison.  At present, this value must always be 0,
00194 *                       indicating a strict comparison.  In the future, other
00195 *                       options may be added.
00196 *
00197 *   tol       double    Tolerance for comparison of floating-point values.
00198 *                       For example, for tol == 1e-6, all floating-point
00199 *                       values in the structs must be equal to the first 6
00200 *                       decimal places.  A value of 0 implies exact equality.
00201 *
00202 *   tab1      const struct tabprm*
00203 *                       The first tabprm struct to compare.
00204 *
00205 *   tab2      const struct tabprm*
00206 *                       The second tabprm struct to compare.
00207 *
00208 * Returned:
00209 *   equal     int*      Non-zero when the given structs are equal.
00210 *
00211 * Function return value:
00212 *             int       Status return value:
00213 *                         0: Success.
00214 *                         1: Null pointer passed.
00215 *
00216 *
00217 * tabfree() - Destructor for the tabprm struct
00218 * --------------------------------------------
00219 * tabfree() frees memory allocated for the tabprm arrays by tabini().
00220 * tabini() records the memory it allocates and tabfree() will only attempt to
00221 * free this.
00222 *
00223 * PLEASE NOTE: tabfree() must not be invoked on a tabprm struct that was not
00224 * initialized by tabini().
00225 *
00226 * Returned:
00227 *   tab       struct tabprm*
00228 *                       Coordinate transformation parameters.
00229 *
00230 * Function return value:
00231 *             int       Status return value:
00232 *                         0: Success.
00233 *                         1: Null tabprm pointer passed.
00234 *
00235 *
00236 * tabsize() - Compute the size of a tabprm struct
00237 * -----------------------------------------------
00238 * tabsize() computes the full size of a tabprm struct, including allocated
00239 * memory.
00240 *
00241 * Given:
00242 *   tab       const struct tabprm*
00243 *                       Tabular transformation parameters.
00244 *
00245 *                       If NULL, the base size of the struct and the allocated
00246 *                       size are both set to zero.
00247 *
00248 * Returned:
```

```
00249 *   sizes     int[2]    The first element is the base size of the struct as
00250 *                       returned by sizeof(struct tabprm).  The second element
00251 *                       is the total allocated size, in bytes, assuming that
00252 *                       the allocation was done by tabini().  This figure
00253 *                       includes memory allocated for the constituent struct,
00254 *                       tabprm::err.
00255 *
00256 *                       It is not an error for the struct not to have been set
00257 *                       up via tabset(), which normally results in additional
00258 *                       memory allocation.
00259 *
00260 * Function return value:
00261 *             int       Status return value:
00262 *                         0: Success.
00263 *
00264 *
00265 * tabprt() - Print routine for the tabprm struct
00266 * ----------------------------------------------
00267 * tabprt() prints the contents of a tabprm struct using wcsprintf().  Mainly
00268 * intended for diagnostic purposes.
00269 *
00270 * Given:
00271 *   tab       const struct tabprm*
00272 *                       Tabular transformation parameters.
00273 *
00274 * Function return value:
00275 *             int       Status return value:
00276 *                         0: Success.
00277 *                         1: Null tabprm pointer passed.
00278 *
00279 *
00280 * tabperr() - Print error messages from a tabprm struct
00281 * -----------------------------------------------------
00282 * tabperr() prints the error message(s) (if any) stored in a tabprm struct.
00283 * If there are no errors then nothing is printed.  It uses wcserr_prt(), q.v.
00284 *
00285 * Given:
00286 *   tab       const struct tabprm*
00287 *                       Tabular transformation parameters.
00288 *
00289 *   prefix    const char *
00290 *                       If non-NULL, each output line will be prefixed with
00291 *                       this string.
00292 *
00293 * Function return value:
00294 *             int       Status return value:
00295 *                         0: Success.
00296 *                         1: Null tabprm pointer passed.
00297 *
00298 *
00299 * tabset() - Setup routine for the tabprm struct
00300 * ----------------------------------------------
00301 * tabset() allocates memory for work arrays in the tabprm struct and sets up
00302 * the struct according to information supplied within it.
00303 *
00304 * Note that this routine need not be called directly; it will be invoked by
00305 * tabx2s() and tabs2x() if tabprm::flag is anything other than a predefined
00306 * magic value.
00307 *
00308 * Given and returned:
00309 *   tab       struct tabprm*
00310 *                       Tabular transformation parameters.
00311 *
00312 * Function return value:
00313 *             int       Status return value:
00314 *                         0: Success.
00315 *                         1: Null tabprm pointer passed.
00316 *                         3: Invalid tabular parameters.
00317 *
00318 *                       For returns > 1, a detailed error message is set in
00319 *                       tabprm::err if enabled, see wcserr_enable().
00320 *
00321 *
00322 * tabx2s() - Pixel-to-world transformation
00323 * ---------------------------------------
00324 * tabx2s() transforms intermediate world coordinates to world coordinates
00325 * using coordinate lookup.
00326 *
00327 * Given and returned:
00328 *   tab       struct tabprm*
00329 *                       Tabular transformation parameters.
00330 *
00331 * Given:
00332 *   ncoord,
00333 *   nelem     int       The number of coordinates, each of vector length
00334 *                       nelem.
00335 *
```

```
00336 *   x          const double[ncoord][nelem]
00337 *                      Array of intermediate world coordinates, SI units.
00338 *
00339 * Returned:
00340 *   world      double[ncoord][nelem]
00341 *                      Array of world coordinates, in SI units.
00342 *
00343 *   stat       int[ncoord]
00344 *                      Status return value status for each coordinate:
00345 *                        0: Success.
00346 *                        1: Invalid intermediate world coordinate.
00347 *
00348 * Function return value:
00349 *             int        Status return value:
00350 *                        0: Success.
00351 *                        1: Null tabprm pointer passed.
00352 *                        3: Invalid tabular parameters.
00353 *                        4: One or more of the x coordinates were invalid,
00354 *                           as indicated by the stat vector.
00355 *
00356 *                      For returns > 1, a detailed error message is set in
00357 *                      tabprm::err if enabled, see wcserr_enable().
00358 *
00359 *
00360 * tabs2x() - World-to-pixel transformation
00361 * ----------------------------------------
00362 * tabs2x() transforms world coordinates to intermediate world coordinates.
00363 *
00364 * Given and returned:
00365 *   tab        struct tabprm*
00366 *                      Tabular transformation parameters.
00367 *
00368 * Given:
00369 *   ncoord,
00370 *   nelem      int        The number of coordinates, each of vector length
00371 *                      nelem.
00372 *   world      const double[ncoord][nelem]
00373 *                      Array of world coordinates, in SI units.
00374 *
00375 * Returned:
00376 *   x          double[ncoord][nelem]
00377 *                      Array of intermediate world coordinates, SI units.
00378 *   stat       int[ncoord]
00379 *                      Status return value status for each vector element:
00380 *                        0: Success.
00381 *                        1: Invalid world coordinate.
00382 *
00383 * Function return value:
00384 *             int        Status return value:
00385 *                        0: Success.
00386 *                        1: Null tabprm pointer passed.
00387 *                        3: Invalid tabular parameters.
00388 *                        5: One or more of the world coordinates were
00389 *                           invalid, as indicated by the stat vector.
00390 *
00391 *                      For returns > 1, a detailed error message is set in
00392 *                      tabprm::err if enabled, see wcserr_enable().
00393 *
00394 *
00395 * tabprm struct - Tabular transformation parameters
00396 * ------------------------------------------------
00397 * The tabprm struct contains information required to transform tabular
00398 * coordinates.  It consists of certain members that must be set by the user
00399 * ("given") and others that are set by the WCSLIB routines ("returned").  Some
00400 * of the latter are supplied for informational purposes while others are for
00401 * internal use only.
00402 *
00403 *   int flag
00404 *     (Given and returned) This flag must be set to zero whenever any of the
00405 *     following tabprm structure members are set or changed:
00406 *
00407 *       - tabprm::M (q.v., not normally set by the user),
00408 *       - tabprm::K (q.v., not normally set by the user),
00409 *       - tabprm::map,
00410 *       - tabprm::crval,
00411 *       - tabprm::index,
00412 *       - tabprm::coord.
00413 *
00414 *     This signals the initialization routine, tabset(), to recompute the
00415 *     returned members of the tabprm struct.  tabset() will reset flag to
00416 *     indicate that this has been done.
00417 *
00418 *     PLEASE NOTE: flag should be set to -1 when tabini() is called for the
00419 *     first time for a particular tabprm struct in order to initialize memory
00420 *     management.  It must ONLY be used on the first initialization otherwise
00421 *     memory leaks may result.
00422 *
```

```
00423 *   int M
00424 *     (Given or returned) Number of tabular coordinate axes.
00425 *
00426 *     If tabini() is used to initialize the tabprm struct (as would normally
00427 *     be the case) then it will set M from the value passed to it as a
00428 *     function argument.  The user should not subsequently modify it.
00429 *
00430 *   int *K
00431 *     (Given or returned) Pointer to the first element of a vector of length
00432 *     tabprm::M whose elements (K_1, K_2,... K_M) record the lengths of the
00433 *     axes of the coordinate array and of each indexing vector.
00434 *
00435 *     If tabini() is used to initialize the tabprm struct (as would normally
00436 *     be the case) then it will set K from the array passed to it as a
00437 *     function argument.  The user should not subsequently modify it.
00438 *
00439 *   int *map
00440 *     (Given) Pointer to the first element of a vector of length tabprm::M
00441 *     that defines the association between axis m in the M-dimensional
00442 *     coordinate array (1 <= m <= M) and the indices of the intermediate world
00443 *     coordinate and world coordinate arrays, x[] and world[], in the argument
00444 *     lists for tabx2s() and tabs2x().
00445 *
00446 *     When x[] and world[] contain the full complement of coordinate elements
00447 *     in image-order, as will usually be the case, then map[m-1] == i-1 for
00448 *     axis i in the N-dimensional image (1 <= i <= N).  In terms of the FITS
00449 *     keywords
00450 *
00451 *       map[PVi_3a - 1] == i - 1.
00452 *
00453 *     However, a different association may result if x[], for example, only
00454 *     contains a (relevant) subset of intermediate world coordinate elements.
00455 *     For example, if M == 1 for an image with N > 1, it is possible to fill
00456 *     x[] with the relevant coordinate element with nelem set to 1.  In this
00457 *     case map[0] = 0 regardless of the value of i.
00458 *
00459 *   double *crval
00460 *     (Given) Pointer to the first element of a vector of length tabprm::M
00461 *     whose elements contain the index value for the reference pixel for each
00462 *     of the tabular coordinate axes.
00463 *
00464 *   double **index
00465 *     (Given) Pointer to the first element of a vector of length tabprm::M of
00466 *     pointers to vectors of lengths (K_1, K_2,... K_M) of 0-relative indexes
00467 *     (see tabprm::K).
00468 *
00469 *     The address of any or all of these index vectors may be set to zero,
00470 *     i.e.
00471 *
00472 =       index[m] == 0;
00473 *
00474 *     this is interpreted as default indexing, i.e.
00475 *
00476 =       index[m][k] = k;
00477 *
00478 *   double *coord
00479 *     (Given) Pointer to the first element of the tabular coordinate array,
00480 *     treated as though it were defined as
00481 *
00482 =       double coord[K_M]...[K_2][K_1][M];
00483 *
00484 *     (see tabprm::K) i.e. with the M dimension varying fastest so that the
00485 *     M elements of a coordinate vector are stored contiguously in memory.
00486 *
00487 *   int nc
00488 *     (Returned) Total number of coordinate vectors in the coordinate array
00489 *     being the product K_1 * K_2 * ... * K_M (see tabprm::K).
00490 *
00491 *   int padding
00492 *     (An unused variable inserted for alignment purposes only.)
00493 *
00494 *   int *sense
00495 *     (Returned) Pointer to the first element of a vector of length tabprm::M
00496 *     whose elements indicate whether the corresponding indexing vector is
00497 *     monotonic increasing (+1), or decreasing (-1).
00498 *
00499 *   int *p0
00500 *     (Returned) Pointer to the first element of a vector of length tabprm::M
00501 *     of interpolated indices into the coordinate array such that Upsilon_m,
00502 *     as defined in Paper III, is equal to (p0[m] + 1) + tabprm::delta[m].
00503 *
00504 *   double *delta
00505 *     (Returned) Pointer to the first element of a vector of length tabprm::M
00506 *     of interpolated indices into the coordinate array such that Upsilon_m,
00507 *     as defined in Paper III, is equal to (tabprm::p0[m] + 1) + delta[m].
00508 *
00509 *   double *extrema
```

```
00510 *     (Returned) Pointer to the first element of an array that records the
00511 *     minimum and maximum value of each element of the coordinate vector in
00512 *     each row of the coordinate array, treated as though it were defined as
00513 *
00514 =       double extrema[K_M]...[K_2][2][M]
00515 *
00516 *     (see tabprm::K).  The minimum is recorded in the first element of the
00517 *     compressed K_1 dimension, then the maximum.  This array is used by the
00518 *     inverse table lookup function, tabs2x(), to speed up table searches.
00519 *
00520 *   struct wcserr *err
00521 *     (Returned) If enabled, when an error status is returned, this struct
00522 *     contains detailed information about the error, see wcserr_enable().
00523 *
00524 *   int m_flag
00525 *     (For internal use only.)
00526 *   int m_M
00527 *     (For internal use only.)
00528 *   int m_N
00529 *     (For internal use only.)
00530 *   int set_M
00531 *     (For internal use only.)
00532 *   int m_K
00533 *     (For internal use only.)
00534 *   int m_map
00535 *     (For internal use only.)
00536 *   int m_crval
00537 *     (For internal use only.)
00538 *   int m_index
00539 *     (For internal use only.)
00540 *   int m_indxs
00541 *     (For internal use only.)
00542 *   int m_coord
00543 *     (For internal use only.)
00544 *
00545 *
00546 * Global variable: const char *tab_errmsg[] - Status return messages
00547 * ---------------------------------------------------------------------
00548 * Error messages to match the status value returned from each function.
00549 *
00550 *===========================================================================*/

6.23.1 Detailed Description

Routines in this suite implement the FITS World Coordinate System (WCS) standard which defines methods to be used for computing world coordinates from image pixel coordinates, and vice versa. The standard, and proposed extensions for handling distortions, are described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)

"Representations of distortions in FITS world coordinate systems",
Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
available from http://www.atnf.csiro.au/people/Mark.Calabretta

"Mapping on the HEALPix grid",
Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865 (WCS Paper V)

"Representing the 'Butterfly' Projection in FITS -- Projection Code XPH",
Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050 (WCS Paper VI)

"Representations of time coordinates in FITS -
 Time and relative dimension in space",
Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
```

These routines are based on the wcsprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

wcsnpv(), wcsnps(), wcsini(), wcsinit(), wcssub(), wcsfree(), and wcstrim(), are provided to manage the wcsprm struct, wcssize() computes its total size including allocated memory, and wcsprt() prints its contents. Refer to the description of the wcsprm struct for an explanation of the anticipated usage of these routines. wcscopy(), which does a deep copy of one wcsprm struct to another, is defined as a preprocessor macro function that invokes wcssub().

wcsperr() prints the error message(s) (if any) stored in a wcsprm struct, and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains.

A setup routine, wcsset(), computes intermediate values in the wcsprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by wcsset() but this need not be called explicitly - refer to the explanation of wcsprm::flag.

wcsp2s() and wcss2p() implement the WCS world coordinate transformations. In fact, they are high level driver routines for the WCS linear, logarithmic, celestial, spectral and tabular transformation routines described in lin.h, log.h, cel.h, spc.h and tab.h.

Given either the celestial longitude or latitude plus an element of the pixel coordinate a hybrid routine, wcsmix(), iteratively solves for the unknown elements.

wcsccs() changes the celestial coordinate system of a wcsprm struct, for example, from equatorial to galactic, and wcssptr() translates the spectral axis. For example, a '**FREQ**' axis may be translated into **'ZOPT-F2W'** and vice versa.

wcslib_version() returns the WCSLIB version number.

Quadcube projections:
The quadcube projections (**TSC**, **CSC**, **QSC**) may be represented in FITS in either of two ways:

a: The six faces may be laid out in one plane and numbered as follows:

```
        0

4  3  2  1  4  3  2

        5
```

Faces 2, 3 and 4 may appear on one side or the other (or both). The world-to-pixel routines map faces 2, 3 and 4 to the left but the pixel-to-world routines accept them on either side.

b: The "COBE" convention in which the six faces are stored in a three-dimensional structure using a **CUBEFACE** axis indexed from 0 to 5 as above.

These routines support both methods; wcsset() determines which is being used by the presence or absence of a **CUBEFACE** axis in ctype[]. wcsp2s() and wcss2p() translate the **CUBEFACE** axis representation to the single plane representation understood by the lower-level WCSLIB projection routines.

6.23.2 Macro Definition Documentation

WCSSUB_LONGITUDE

```
#define WCSSUB_LONGITUDE 0x1001
```

Mask for extraction of longitude axis by wcssub().

Mask to use for extracting the longitude axis when sub-imaging, refer to the *axes* argument of wcssub().

WCSSUB_LATITUDE

```
#define WCSSUB_LATITUDE 0x1002
```

Mask for extraction of latitude axis by wcssub().

Mask to use for extracting the latitude axis when sub-imaging, refer to the *axes* argument of wcssub().

WCSSUB_CUBEFACE

```
#define WCSSUB_CUBEFACE 0x1004
```

Mask for extraction of **CUBEFACE** axis by wcssub().

Mask to use for extracting the **CUBEFACE** axis when sub-imaging, refer to the *axes* argument of wcssub().

WCSSUB_CELESTIAL

```
#define WCSSUB_CELESTIAL 0x1007
```

Mask for extraction of celestial axes by wcssub().

Mask to use for extracting the celestial axes (longitude, latitude and cubeface) when sub-imaging, refer to the *axes* argument of wcssub().

WCSSUB_SPECTRAL

```
#define WCSSUB_SPECTRAL 0x1008
```

Mask for extraction of spectral axis by wcssub().

Mask to use for extracting the spectral axis when sub-imaging, refer to the *axes* argument of wcssub().

WCSSUB_STOKES

```
#define WCSSUB_STOKES 0x1010
```

Mask for extraction of **STOKES** axis by wcssub().

Mask to use for extracting the **STOKES** axis when sub-imaging, refer to the *axes* argument of wcssub().

WCSSUB_TIME

```
#define WCSSUB_TIME 0x1020
```

WCSCOMPARE_ANCILLARY

```
#define WCSCOMPARE_ANCILLARY 0x0001
```

WCSCOMPARE_TILING

```
#define WCSCOMPARE_TILING 0x0002
```

WCSCOMPARE_CRPIX

```
#define WCSCOMPARE_CRPIX 0x0004
```

PVLEN

```
#define PVLEN (sizeof(struct pvcard)/sizeof(int))
```

PSLEN

```
#define PSLEN (sizeof(struct pscard)/sizeof(int))
```

AUXLEN

```
#define AUXLEN (sizeof(struct auxprm)/sizeof(int))
```

WCSLEN

```
#define WCSLEN (sizeof(struct wcsprm)/sizeof(int))
```

Size of the wcsprm struct in int units.

Size of the wcsprm struct in *int* units, used by the Fortran wrappers.

wcscopy

```
#define wcscopy(
              alloc,
              wcssrc,
              wcsdst ) wcssub(alloc, wcssrc, 0x0, 0x0, wcsdst)
```

Copy routine for the wcsprm struct.

wcscopy() does a deep copy of one wcsprm struct to another. As of WCSLIB 3.6, it is implemented as a preprocessor macro that invokes wcssub() with the nsub and axes pointers both set to zero.

wcsini_errmsg

```
#define wcsini_errmsg wcs_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcssub_errmsg

```
#define wcssub_errmsg wcs_errmsg
```

6.23.4 Function Documentation

wcsnpv()

```
int wcsnpv (
            int n )
```

Memory allocation for **PV**i_ma.

wcsnpv() sets or gets the value of NPVMAX (default 64). This global variable controls the number of pvcard structs, for holding **PV**i_ma keyvalues, that wcsini() should allocate space for. It is also used by wcsinit() as the default value of npvmax.

PLEASE NOTE: This function is not thread-safe.

Parameters

in	*n*	Value of NPVMAX; ignored if < 0. Use a value less than zero to get the current value.

Returns

Current value of NPVMAX.

wcsnps()

```
int wcsnps (
            int n )
```

Memory allocation for **PS**i_ma.

wcsnps() sets or gets the value of NPSMAX (default 8). This global variable controls the number of pscard structs, for holding **PS**i_ma keyvalues, that wcsini() should allocate space for. It is also used by wcsinit() as the default value of npsmax.

PLEASE NOTE: This function is not thread-safe.

Parameters

in	*n*	Value of NPSMAX; ignored if < 0. Use a value less than zero to get the current value.

Returns

Current value of NPSMAX.

wcsini()

```
int wcsini (
            int alloc,
            int naxis,
            struct wcsprm * wcs )
```

Default constructor for the wcsprm struct.

wcsini() is a thin wrapper on **wcsinit**(). It invokes it with npvmax, npsmax, and ndpmax set to -1 which causes it to use the values of the global variables NDPMAX, NPSMAX, and NDPMAX. It is thereby potentially thread-unsafe if these variables are altered dynamically via wcsnpv(), wcsnps(), and disndp(). Use **wcsinit**() for a thread-safe alternative in this case.

wcsinit()

```
int wcsinit (
             int alloc,
             int naxis,
             struct wcsprm * wcs,
             int npvmax,
             int npsmax,
             int ndpmax )
```

Default constructor for the wcsprm struct.

wcsinit() optionally allocates memory for arrays in a wcsprm struct and sets all members of the struct to default values.

PLEASE NOTE: every wcsprm struct should be initialized by **wcsinit**(), possibly repeatedly. On the first invokation, and only the first invokation, wcsprm::flag must be set to -1 to initialize memory management, regardless of whether **wcsinit**() will actually be used to allocate memory.

Parameters

in	*alloc*	If true, allocate memory unconditionally for the crpix, etc. arrays. Please note that memory is never allocated by **wcsinit**() for the auxprm, tabprm, nor wtbarr structs. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	*naxis*	The number of world coordinate axes. This is used to determine the length of the various wcsprm vectors and matrices and therefore the amount of memory to allocate for them.
in,out	*wcs*	Coordinate transformation parameters. Note that, in order to initialize memory management, wcsprm::flag should be set to -1 when wcs is initialized for the first time (memory leaks may result if it had already been initialized).
in	*npvmax*	The number of **PV**i_ma keywords to allocate space for. If set to -1, the value of the global variable NPVMAX will be used. This is potentially thread-unsafe if wcsnpv() is being used dynamically to alter its value.
in	*npsmax*	The number of **PS**i_ma keywords to allocate space for. If set to -1, the value of the global variable NPSMAX will be used. This is potentially thread-unsafe if wcsnps() is being used dynamically to alter its value.
in	*ndpmax*	The number of DPja or DQia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.

For returns $>$ 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcsauxi()

```
int wcsauxi (
             int alloc,
             struct wcsprm * wcs )
```

Default constructor for the auxprm struct.

wcsauxi() optionally allocates memory for an auxprm struct, attaches it to wcsprm, and sets all members of the struct to default values.

Parameters

in	*alloc*	If true, allocate memory unconditionally for the auxprm struct. If false, it is assumed that wcsprm::aux has already been set to point to an auxprm struct, in which case the user is responsible for managing that memory. However, if wcsprm::aux is a null pointer, memory will be allocated regardless. (In other words, setting alloc true saves having to initalize the pointer to zero.)
in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.

wcssub()

```
int wcssub (
             int alloc,
             const struct wcsprm * wcssrc,
             int * nsub,
             int axes[],
             struct wcsprm * wcsdst )
```

Subimage extraction routine for the wcsprm struct.

wcssub() extracts the coordinate description for a subimage from a wcsprm struct. It does a deep copy, using wcsinit() to allocate memory for its arrays if required. Only the "information to be provided" part of the struct is extracted. Consequently, wcsset() need not have been, and won't be invoked on the struct from which the subimage is extracted. A call to wcsset() is required to set up the subimage struct.

The world coordinate system of the subimage must be separable in the sense that the world coordinates at any point in the subimage must depend only on the pixel coordinates of the axes extracted. In practice, this means that the linear transformation matrix of the original image must not contain non-zero off-diagonal terms that associate any of the subimage axes with any of the non-subimage axes. Likewise, if any distortions are associated with the subimage axes, they must not depend on any of the axes that are not being extracted.

Note that while the required elements of the tabprm array are extracted, the wtbarr array is not. (Thus it is not appropriate to call **wcssub**() after wcstab() but before filling the tabprm structs - refer to wcshdr.h.)

wcssub() can also add axes to a wcsprm struct. The new axes will be created using the defaults set by wcsinit() which produce a simple, unnamed, linear axis with world coordinate equal to the pixel coordinate. These default values can be changed afterwards, before invoking wcsset().

Parameters

in	*alloc*	If true, allocate memory for the crpix, etc. arrays in the destination. Otherwise, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless.
in	*wcssrc*	Struct to extract from.
in,out	*nsub*	
in,out	*axes*	Vector of length ∗nsub containing the image axis numbers (1-relative) to extract. Order is significant; axes[0] is the axis number of the input image that corresponds to the first axis in the subimage, etc. Use an axis number of 0 to create a new axis using the defaults set by wcsinit(). They can be changed later. nsub (the pointer) may be set to zero, and so also may ∗nsub, which is interpreted to mean all axes in the input image; the number of axes will be returned if nsub != 0x0. axes itself (the pointer) may be set to zero to indicate the first ∗nsub axes in their original order. Set both nsub (or ∗nsub) and axes to zero to do a deep copy of one wcsprm struct to another. Subimage extraction by coordinate axis type may be done by setting the elements of axes[] to the following special preprocessor macro values: • WCSSUB_LONGITUDE: Celestial longitude. • WCSSUB_LATITUDE: Celestial latitude. • WCSSUB_CUBEFACE: Quadcube **CUBEFACE** axis. • WCSSUB_SPECTRAL: Spectral axis. • WCSSUB_STOKES: Stokes axis. • WCSSUB_TIME: Time axis. Refer to the notes (below) for further usage examples. On return, ∗nsub will be set to the number of axes in the subimage; this may be zero if there were no axes of the required type(s) (in which case no memory will be allocated). axes[] will contain the axis numbers that were extracted, or 0 for newly created axes. The vector length must be sufficient to contain all axis numbers. No checks are performed to verify that the coordinate axes are consistent, this is done by wcsset().
in,out	*wcsdst*	Struct describing the subimage. wcsprm::flag should be set to -1 if wcsdst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 12: Invalid subimage specification.
- 13: Non-separable subimage coordinate system.

For returns $>$ 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

Notes:

1. Combinations of subimage axes of particular types may be extracted in the same order as they occur in the input image by combining preprocessor codes, for example

```
*nsub = 1;
axes[0] = WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_SPECTRAL;
```

   would extract the longitude, latitude, and spectral axes in the same order as the input image. If one of each were present, *nsub = 3 would be returned.

   For convenience, WCSSUB_CELESTIAL is defined as the combination WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_CUBEFACE.

   The codes may also be negated to extract all but the types specified, for example

```
*nsub = 4;
axes[0] = WCSSUB_LONGITUDE;
axes[1] = WCSSUB_LATITUDE;
axes[2] = WCSSUB_CUBEFACE;
axes[3] = -(WCSSUB_SPECTRAL | WCSSUB_STOKES);
```

   The last of these specifies all axis types other than spectral or Stokes. Extraction is done in the order specified by axes[] a longitude axis (if present) would be extracted first (via axes[0]) and not subsequently (via axes[3]). Likewise for the latitude and cubeface axes in this example.

   From the foregoing, it is apparent that the value of *nsub returned may be less than or greater than that given. However, it will never exceed the number of axes in the input image (plus the number of newly-created axes if any were specified on input).

wcscompare()

```
int wcscompare (
            int cmp,
            double tol,
            const struct wcsprm * wcs1,
            const struct wcsprm * wcs2,
            int * equal )
```

Compare two wcsprm structs for equality.

wcscompare() compares two wcsprm structs for equality.

Parameters

in	*cmp*	A bit field controlling the strictness of the comparison. When 0, all fields must be identical. The following constants may be or'ed together to relax the comparison: • WCSCOMPARE_ANCILLARY: Ignore ancillary keywords that don't change the WCS transformation, such as **DATE-OBS** or EQUINOX. • WCSCOMPARE_TILING: Ignore integral differences in **CRPIX**ja. This is the 'tiling' condition, where two WCSes cover different regions of the same map projection and align on the same map grid. • WCSCOMPARE_CRPIX: Ignore any differences at all in **CRPIX**ja. The two WCSes cover different regions of the same map projection but may not align on the same map grid. Overrides WCSCOMPARE_TILING.
in	*tol*	Tolerance for comparison of floating-point values. For example, for tol == 1e-6, all floating-point values in the structs must be equal to the first 6 decimal places. A value of 0 implies exact equality.
in	*wcs1*	The first wcsprm struct to compare.
in	*wcs2*	The second wcsprm struct to compare.
out	*equal*	Non-zero when the given structs are equal.

Returns

Status return value:

- 0: Success.
- 1: Null pointer passed.

wcsfree()

```
int wcsfree (
             struct wcsprm * wcs )
```

Destructor for the wcsprm struct.

wcsfree() frees memory allocated for the wcsprm arrays by wcsinit() and/or wcsset(). wcsinit() records the memory it allocates and **wcsfree**() will only attempt to free this.

PLEASE NOTE: wcsfree() must not be invoked on a wcsprm struct that was not initialized by wcsinit().

Parameters

in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcstrim()

```
int wcstrim (
             struct wcsprm * wcs )
```

Free unused arrays in the wcsprm struct.

wcstrim() frees memory allocated by wcsinit() for arrays in the wcsprm struct that remains unused after it has been set up by wcsset().

The free'd array members are associated with FITS WCS keyrecords that are rarely used and usually just bloat the struct: wcsprm::crota, wcsprm::colax, wcsprm::cname, wcsprm::crder, wcsprm::csyer, wcsprm::czphs, and wcsprm::cperi. If unused, wcsprm::pv, wcsprm::ps, and wcsprm::cd are also freed.

Once these arrays have been freed, a test such as
```
if (!undefined(wcs->cname[i])) {...}
```

must be protected as follows
```
if (wcs->cname && !undefined(wcs->cname[i])) {...}
```

In addition, if wcsprm::npv is non-zero but less than wcsprm::npvmax, then the unused space in wcsprm::pv will be recovered (using realloc()). Likewise for wcsprm::ps.

Parameters

in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 14: wcsprm struct is unset.

wcssize()

```
int wcssize (
             const struct wcsprm * wcs,
             int sizes[2] )
```

Compute the size of a wcsprm struct.

wcssize() computes the full size of a wcsprm struct, including allocated memory.

Parameters

in	*wcs*	Coordinate transformation parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct wcsprm). The second element is the total allocated size, in bytes, assuming that the allocation was done by wcsini(). This figure includes memory allocated for members of constituent structs, such as wcsprm::lin. It is not an error for the struct not to have been set up via wcsset(), which normally results in additional memory allocation.

Returns

Status return value:

- 0: Success.

auxsize()

```
int auxsize (
             const struct auxprm * aux,
             int sizes[2] )
```

Compute the size of a auxprm struct.

auxsize() computes the full size of an auxprm struct, including allocated memory.

Parameters

in	*aux*	Auxiliary coordinate information. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct auxprm). The second element is the total allocated size, in bytes, currently zero.

Returns

Status return value:

- 0: Success.

wcsprt()

```
int wcsprt (
            const struct wcsprm * wcs )
```

Print routine for the wcsprm struct.

wcsprt() prints the contents of a wcsprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsperr()

```
int wcsperr (
            const struct wcsprm * wcs,
            const char * prefix )
```

Print error messages from a wcsprm struct.

wcsperr() prints the error message(s), if any, stored in a wcsprm struct, and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	*wcs*	Coordinate transformation parameters.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsbchk()

```
int wcsbchk (
             struct wcsprm * wcs,
             int bounds )
```

Enable/disable bounds checking.

wcsbchk() is used to control bounds checking in the projection routines. Note that wcsset() always enables bounds checking. **wcsbchk**() will invoke wcsset() on the wcsprm struct beforehand if necessary.

Parameters

in,out	*wcs*	Coordinate transformation parameters.
in	*bounds*	If bounds&1 then enable strict bounds checking for the spherical-to-Cartesian (s2x) transformation for the AZP, SZP, TAN, **SIN**, ZPN, and COP projections. If bounds&2 then enable strict bounds checking for the Cartesian-to-spherical (x2s) transformation for the HPX and XPH projections. If bounds&4 then enable bounds checking on the native coordinates returned by the Cartesian-to-spherical (x2s) transformations using prjchk(). Zero it to disable all checking.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsset()

```
int wcsset (
             struct wcsprm * wcs )
```

Setup routine for the wcsprm struct.

wcsset() sets up a wcsprm struct according to information supplied within it (refer to the description of the wcsprm struct).

wcsset() recognizes the **NCP** projection and converts it to the equivalent **SIN** projection and likewise translates **GLS** into **SFL**. It also translates the AIPS spectral types (**'FREQ-LSR'**, **'FELO-HEL'**, etc.), possibly changing the input header keywords wcsprm::ctype and/or wcsprm::specsys if necessary.

Note that this routine need not be called directly; it will be invoked by wcsp2s() and wcss2p() if the wcsprm::flag is anything other than a predefined magic value.

Parameters

in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

Notes:

1. **wcsset**() always enables strict bounds checking in the projection routines (via a call to prjini()). Use wcsbchk() to modify bounds-checking after **wcsset**() is invoked.

wcsp2s()

```
int wcsp2s (
             struct wcsprm * wcs,
             int ncoord,
             int nelem,
             const double pixcrd[],
             double imgcrd[],
             double phi[],
             double theta[],
             double world[],
             int stat[] )
```

Pixel-to-world transformation.

wcsp2s() transforms pixel coordinates to world coordinates.

Parameters

in,out	*wcs*	Coordinate transformation parameters.
in	*ncoord,nelem*	The number of coordinates, each of vector length nelem but containing wcs.naxis coordinate elements. Thus nelem must equal or exceed the value of the **NAXIS** keyword unless ncoord == 1, in which case nelem is not used.
in	*pixcrd*	Array of pixel coordinates.

Parameters

out	*imgcrd*	Array of intermediate world coordinates. For celestial axes, imgcrd[][wcs.lng] and imgcrd[][wcs.lat] are the projected x-, and y-coordinates in pseudo "degrees". For spectral axes, imgcrd[][wcs.spec] is the intermediate spectral coordinate, in SI units. For time axes, imgcrd[][wcs.time] is the intermediate time coordinate.
out	*phi,theta*	Longitude and latitude in the native coordinate system of the projection [deg].
out	*world*	Array of world coordinates. For celestial axes, world[][wcs.lng] and world[][wcs.lat] are the celestial longitude and latitude [deg]. For spectral axes, world[][wcs.spec] is the spectral coordinate, in SI units. For time axes, world[][wcs.time] is the time coordinate.
out	*stat*	Status return value for each coordinate: • 0: Success. 1+: A bit mask indicating invalid pixel coordinate element(s).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 8: One or more of the pixel coordinates were invalid, as indicated by the stat vector.

For returns $>$ 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcss2p()

```
int wcss2p (
            struct wcsprm * wcs,
            int ncoord,
            int nelem,
            const double world[],
            double phi[],
            double theta[],
            double imgcrd[],
            double pixcrd[],
            int stat[] )
```

World-to-pixel transformation.

wcss2p() transforms world coordinates to pixel coordinates.

Parameters

in,out	*wcs*	Coordinate transformation parameters.

Parameters

in	*ncoord,nelem*	The number of coordinates, each of vector length nelem but containing wcs.naxis coordinate elements. Thus nelem must equal or exceed the value of the **NAXIS** keyword unless ncoord == 1, in which case nelem is not used.
in	*world*	Array of world coordinates. For celestial axes, world[][wcs.lng] and world[][wcs.lat] are the celestial longitude and latitude [deg]. For spectral axes, world[][wcs.spec] is the spectral coordinate, in SI units. For time axes, world[][wcs.time] is the time coordinate.
out	*phi,theta*	Longitude and latitude in the native coordinate system of the projection [deg].
out	*imgcrd*	Array of intermediate world coordinates. For celestial axes, imgcrd[][wcs.lng] and imgcrd[][wcs.lat] are the projected x-, and y-coordinates in pseudo "degrees". For quadcube projections with a **CUBEFACE** axis the face number is also returned in imgcrd[][wcs.cubeface]. For spectral axes, imgcrd[][wcs.spec] is the intermediate spectral coordinate, in SI units. For time axes, imgcrd[][wcs.time] is the intermediate time coordinate.
out	*pixcrd*	Array of pixel coordinates.
out	*stat*	Status return value for each coordinate: • 0: Success. 1+: A bit mask indicating invalid world coordinate element(s).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 9: One or more of the world coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcsmix()

```
int wcsmix (
              struct wcsprm * wcs,
              int mixpix,
              int mixcel,
              const double vspan[2],
              double vstep,
              int viter,
              double world[],
              double phi[],
              double theta[],
              double imgcrd[],
              double pixcrd[] )
```

Hybrid coordinate transformation.

wcsmix(), given either the celestial longitude or latitude plus an element of the pixel coordinate, solves for the remaining elements by iterating on the unknown celestial coordinate element using wcss2p(). Refer also to the notes below.

Parameters

in,out	*wcs*	Indices for the celestial coordinates obtained by parsing the wcsprm::ctype[].
in	*mixpix*	Which element of the pixel coordinate is given.
in	*mixcel*	Which element of the celestial coordinate is given: • 1: Celestial longitude is given in world[wcs.lng], latitude returned in world[wcs.lat]. • 2: Celestial latitude is given in world[wcs.lat], longitude returned in world[wcs.lng].
in	*vspan*	Solution interval for the celestial coordinate [deg]. The ordering of the two limits is irrelevant. Longitude ranges may be specified with any convenient normalization, for example [-120,+120] is the same as [240,480], except that the solution will be returned with the same normalization, i.e. lie within the interval specified.
in	*vstep*	Step size for solution search [deg]. If zero, a sensible, although perhaps non-optimal default will be used.
in	*viter*	If a solution is not found then the step size will be halved and the search recommenced. viter controls how many times the step size is halved. The allowed range is 5 - 10.
in,out	*world*	World coordinate elements. world[wcs.lng] and world[wcs.lat] are the celestial longitude and latitude [deg]. Which is given and which returned depends on the value of mixcel. All other elements are given.
out	*phi,theta*	Longitude and latitude in the native coordinate system of the projection [deg].
out	*imgcrd*	Image coordinate elements. imgcrd[wcs.lng] and imgcrd[wcs.lat] are the projected x-, and y-coordinates in pseudo "degrees".
in,out	*pixcrd*	Pixel coordinate. The element indicated by mixpix is given and the remaining elements are returned.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 10: Invalid world coordinate.
- 11: No solution found in the specified interval.

For returns $>$ 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

Notes:

1. Initially the specified solution interval is checked to see if it's a "crossing" interval. If it isn't, a search is made for a crossing solution by iterating on the unknown celestial coordinate starting at the upper limit of the solution interval and decrementing by the specified step size. A crossing is indicated if the trial value of the pixel coordinate steps through the value specified. If a crossing interval is found then the solution is determined by a modified form of "regula falsi" division of the crossing interval. If no crossing interval was found within the specified solution interval then a search is made for a "non-crossing" solution as may arise from a point of tangency. The process is complicated by having to make allowance for the discontinuities that occur in all map projections.

   Once one solution has been determined others may be found by subsequent invokations of **wcsmix**() with suitably restricted solution intervals.

   Note the circumstance that arises when the solution point lies at a native pole of a projection in which the pole is represented as a finite curve, for example the zenithals and conics. In such cases two or more valid solutions may exist but **wcsmix**() only ever returns one.

   Because of its generality **wcsmix**() is very compute-intensive. For compute-limited applications more efficient special-case solvers could be written for simple projections, for example non-oblique cylindrical projections.

wcsccs()

```
int wcsccs (
              struct wcsprm * wcs,
              double lng2p1,
              double lat2p1,
              double lng1p2,
              const char * clng,
              const char * clat,
              const char * radesys,
              double equinox,
              const char * alt )
```

Change celestial coordinate system.

wcsccs() changes the celestial coordinate system of a wcsprm struct. For example, from equatorial to galactic coordinates.

Parameters that define the spherical coordinate transformation, essentially being three Euler angles, must be provided. Thereby **wcsccs**() does not need prior knowledge of specific celestial coordinate systems. It also has the advantage of making it completely general.

Auxiliary members of the wcsprm struct relating to equatorial celestial coordinate systems may also be changed.

Only orthodox spherical coordinate systems are supported. That is, they must be right-handed, with latitude increasing from zero at the equator to +90 degrees at the pole. This precludes systems such as aziumuth and zenith distance, which, however, could be handled as negative azimuth and elevation.

PLEASE NOTE: Information in the wcsprm struct relating to the original coordinate system will be overwritten and therefore lost. If this is undesirable, invoke **wcsccs**() on a copy of the struct made with wcssub(). The wcsprm struct is reset on return with an explicit call to wcsset().

Parameters

in,out	*wcs*	Coordinate transformation parameters. Particular "values to be given" elements of the wcsprm struct are modified.
in	*lng2p1,lat2p1*	Longitude and latitude in the new celestial coordinate system of the pole (i.e. latitude +90) of the original system [deg]. See notes 1 and 2 below.

Parameters

in	*lng1p2*	Longitude in the original celestial coordinate system of the pole (i.e. latitude +90) of the new system [deg]. See note 1 below.
in	*clng,clat*	Longitude and latitude identifiers of the new **CTYPE**ia celestial axis codes, without trailing dashes. For example, "RA" and "DEC" or "GLON" and "GLAT". Up to four characters are used, longer strings need not be null-terminated.
in	*radesys*	Used when transforming to equatorial coordinates, identified by clng == "RA" and clat = "DEC". May be set to the null pointer to preserve the current value. Up to 71 characters are used, longer strings need not be null-terminated. If the new coordinate system is anything other than equatorial, then wcsprm::radesys will be cleared.
in	*equinox*	Used when transforming to equatorial coordinates. May be set to zero to preserve the current value. If the new coordinate system is not equatorial, then wcsprm::equinox will be marked as undefined.
in	*alt*	Character code for alternate coordinate descriptions (i.e. the '**a**' in keyword names such as **CTYPE**ia). This is blank for the primary coordinate description, or one of the 26 upper-case letters, A-Z. May be set to the null pointer, or null string if no change is required.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 12: Invalid subimage specification (no celestial axes).

Notes:

1. Follows the prescription given in WCS Paper II, Sect. 2.7 for changing celestial coordinates.

   The implementation takes account of indeterminacies that arise in that prescription in the particular cases where one of the poles of the new system is at the fiducial point, or one of them is at the native pole.

2. If lat2p1 == +90, i.e. where the poles of the two coordinate systems coincide, then the spherical coordinate transformation becomes a simple change in origin of longitude given by lng2 = lng1 + (lng2p1 - lng1p2 - 180), and lat2 = lat1, where (lng2,lat2) are coordinates in the new system, and (lng1,lat1) are coordinates in the original system.

   Likewise, if lat2p1 == -90, then lng2 = -lng1 + (lng2p1 + lng1p2), and lat2 = -lat1.

3. For example, if the original coordinate system is B1950 equatorial and the desired new coordinate system is galactic, then

   - (lng2p1,lat2p1) are the galactic coordinates of the B1950 celestial pole, defined by the IAU to be (123.↩ 0,+27.4), and lng1p2 is the B1950 right ascension of the galactic pole, defined as 192.25. Clearly these coordinates are fixed for a particular coordinate transformation.
   - (clng,clat) would be '**GLON**' and '**GLAT**', these being the FITS standard identifiers for galactic coordinates.
   - Since the new coordinate system is not equatorial, wcsprm::radesys and wcsprm::equinox will be cleared.

4. The coordinates required for some common transformations (obtained from https://ned.ipac.caltech.edu/coordinate_calculator) are as follows:

```
(123.0000,+27.4000) galactic coordinates of B1950 celestial pole,
(192.2500,+27.4000) B1950 equatorial coordinates of galactic pole.
(122.9319,+27.1283) galactic coordinates of J2000 celestial pole,
(192.8595,+27.1283) J2000 equatorial coordinates of galactic pole.
(359.6774,+89.7217) B1950 equatorial coordinates of J2000 pole,
(180.3162,+89.7217) J2000 equatorial coordinates of B1950 pole.
(270.0000,+66.5542) B1950 equatorial coordinates of B1950 ecliptic pole,
( 90.0000,+66.5542) B1950 ecliptic coordinates of B1950 celestial pole.
(270.0000,+66.5607) J2000 equatorial coordinates of J2000 ecliptic pole,
( 90.0000,+66.5607) J2000 ecliptic coordinates of J2000 celestial pole.
( 26.7315,+15.6441) supergalactic coordinates of B1950 celestial pole,
(283.1894,+15.6441) B1950 equatorial coordinates of supergalactic pole.
( 26.4505,+15.7089) supergalactic coordinates of J2000 celestial pole,
(283.7542,+15.7089) J2000 equatorial coordinates of supergalactic pole.
```

wcssptr()

```
int wcssptr (
             struct wcsprm * wcs,
             int * i,
             char ctype[9] )
```

Spectral axis translation.

wcssptr() translates the spectral axis in a wcsprm struct. For example, a '**FREQ**' axis may be translated into '**ZOPT-F2W**' and vice versa.

PLEASE NOTE: Information in the wcsprm struct relating to the original coordinate system will be overwritten and therefore lost. If this is undesirable, invoke **wcssptr**() on a copy of the struct made with wcssub(). The wcsprm struct is reset on return with an explicit call to wcsset().

Parameters

in,out	*wcs*	Coordinate transformation parameters.
in,out	*i*	Index of the spectral axis (0-relative). If given < 0 it will be set to the first spectral axis identified from the ctype[] keyvalues in the wcsprm struct.
in,out	*ctype*	Desired spectral **CTYPE**ia. Wildcarding may be used as for the ctypeS2 argument to spctrn() as described in the prologue of spc.h, i.e. if the final three characters are specified as "???", or if just the eighth character is specified as '?', the correct algorithm code will be substituted and returned.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 12: Invalid subimage specification (no spectral axis).

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcslib_version()

```
const char * wcslib_version (
             int vers[3] )
```

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wcs routines
00031 * ---------------------------
00032 * Routines in this suite implement the FITS World Coordinate System (WCS)
00033 * standard which defines methods to be used for computing world coordinates
00034 * from image pixel coordinates, and vice versa.  The standard, and proposed
00035 * extensions for handling distortions, are described in
00036 *
00037 =   "Representations of world coordinates in FITS",
00038 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00039 =
00040 =   "Representations of celestial coordinates in FITS",

00061 *
00062 * These routines are based on the wcsprm struct which contains all information
00063 * needed for the computations.  The struct contains some members that must be
00064 * set by the user, and others that are maintained by these routines, somewhat
00065 * like a C++ class but with no encapsulation.
00066 *
00067 * wcsnpv(), wcsnps(), wcsini(), wcsinit(), wcssub(), wcsfree(), and wcstrim(),
00068 * are provided to manage the wcsprm struct, wcssize() computes its total size
00069 * including allocated memory, and wcsprt() prints its contents.  Refer to the
00070 * description of the wcsprm struct for an explanation of the anticipated usage
00071 * of these routines.  wcscopy(), which does a deep copy of one wcsprm struct
00072 * to another, is defined as a preprocessor macro function that invokes
00073 * wcssub().
00074 *
00075 * wcsperr() prints the error message(s) (if any) stored in a wcsprm struct,
00076 * and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains.
00077 *
00078 * A setup routine, wcsset(), computes intermediate values in the wcsprm struct
00079 * from parameters in it that were supplied by the user.  The struct always
00080 * needs to be set up by wcsset() but this need not be called explicitly -
00081 * refer to the explanation of wcsprm::flag.
00082 *
00083 * wcsp2s() and wcss2p() implement the WCS world coordinate transformations.
00084 * In fact, they are high level driver routines for the WCS linear,
00085 * logarithmic, celestial, spectral and tabular transformation routines
00086 * described in lin.h, log.h, cel.h, spc.h and tab.h.
00087 *
00088 * Given either the celestial longitude or latitude plus an element of the
00089 * pixel coordinate a hybrid routine, wcsmix(), iteratively solves for the
00090 * unknown elements.
00091 *
00092 * wcsccs() changes the celestial coordinate system of a wcsprm struct, for
00093 * example, from equatorial to galactic, and wcssptr() translates the spectral
00094 * axis.  For example, a 'FREQ' axis may be translated into 'ZOPT-F2W' and vice
00095 * versa.
00096 *
00097 * wcslib_version() returns the WCSLIB version number.
00098 *
00099 * Quadcube projections:
00100 * ---------------------
00101 *   The quadcube projections (TSC, CSC, QSC) may be represented in FITS in
00102 *   either of two ways:
00103 *
00104 *     a: The six faces may be laid out in one plane and numbered as follows:
00105 *
00106 =                                 0
00107 =
00108 =                         4  3  2  1  4  3  2
00109 =
00110 =                                 5
00111 *
00112 *        Faces 2, 3 and 4 may appear on one side or the other (or both).  The
00113 *        world-to-pixel routines map faces 2, 3 and 4 to the left but the
00114 *        pixel-to-world routines accept them on either side.
00115 *
00116 *     b: The "COBE" convention in which the six faces are stored in a
00117 *        three-dimensional structure using a CUBEFACE axis indexed from
00118 *        0 to 5 as above.
00119 *
00120 *   These routines support both methods; wcsset() determines which is being
00121 *   used by the presence or absence of a CUBEFACE axis in ctype[].  wcsp2s()
00122 *   and wcss2p() translate the CUBEFACE axis representation to the single
00123 *   plane representation understood by the lower-level WCSLIB projection
00124 *   routines.
00125 *
00126 *
00127 * wcsnpv() - Memory allocation for PVi_ma
00128 * ---------------------------------------
00129 * wcsnpv() sets or gets the value of NPVMAX (default 64).  This global
00130 * variable controls the number of pvcard structs, for holding PVi_ma
00131 * keyvalues, that wcsini() should allocate space for.  It is also used by
00132 * wcsinit() as the default value of npvmax.
00133 *
00134 * PLEASE NOTE: This function is not thread-safe.
00135 *
00136 * Given:
00137 *   n         int       Value of NPVMAX; ignored if < 0.  Use a value less
00138 *                       than zero to get the current value.
00139 *
00140 * Function return value:
00141 *             int       Current value of NPVMAX.
00142 *
00143 *
00144 * wcsnps() - Memory allocation for PSi_ma
00145 * ---------------------------------------
00146 * wcsnps() sets or gets the value of NPSMAX (default 8).  This global variable
```

```
00147 * controls the number of pscard structs, for holding PSi_ma keyvalues, that
00148 * wcsini() should allocate space for.  It is also used by wcsinit() as the
00149 * default value of npsmax.
00150 *
00151 * PLEASE NOTE: This function is not thread-safe.
00152 *
00153 * Given:
00154 *   n          int       Value of NPSMAX; ignored if < 0.  Use a value less
00155 *                        than zero to get the current value.
00156 *
00157 * Function return value:
00158 *              int       Current value of NPSMAX.
00159 *
00160 *
00161 * wcsini() - Default constructor for the wcsprm struct
00162 * ----------------------------------------------------
00163 * wcsini() is a thin wrapper on wcsinit().  It invokes it with npvmax,
00164 * npsmax, and ndpmax set to -1 which causes it to use the values of the
00165 * global variables NDPMAX, NPSMAX, and NDPMAX.  It is thereby potentially
00166 * thread-unsafe if these variables are altered dynamically via wcsnpv(),
00167 * wcsnps(), and disndp().  Use wcsinit() for a thread-safe alternative in
00168 * this case.
00169 *
00170 *
00171 * wcsinit() - Default constructor for the wcsprm struct
00172 * ----------------------------------------------------
00173 * wcsinit() optionally allocates memory for arrays in a wcsprm struct and sets
00174 * all members of the struct to default values.
00175 *
00176 * PLEASE NOTE: every wcsprm struct should be initialized by wcsinit(),
00177 * possibly repeatedly.  On the first invokation, and only the first
00178 * invokation, wcsprm::flag must be set to -1 to initialize memory management,
00179 * regardless of whether wcsinit() will actually be used to allocate memory.
00180 *
00181 * Given:
00182 *   alloc      int       If true, allocate memory unconditionally for the
00183 *                        crpix, etc. arrays.  Please note that memory is never
00184 *                        allocated by wcsinit() for the auxprm, tabprm, nor
00185 *                        wtbarr structs.
00186 *
00187 *                        If false, it is assumed that pointers to these arrays
00188 *                        have been set by the user except if they are null
00189 *                        pointers in which case memory will be allocated for
00190 *                        them regardless.  (In other words, setting alloc true
00191 *                        saves having to initalize these pointers to zero.)
00192 *
00193 *   naxis      int       The number of world coordinate axes.  This is used to
00194 *                        determine the length of the various wcsprm vectors and
00195 *                        matrices and therefore the amount of memory to
00196 *                        allocate for them.
00197 *
00198 * Given and returned:
00199 *   wcs        struct wcsprm*
00200 *                        Coordinate transformation parameters.
00201 *
00202 *                        Note that, in order to initialize memory management,
00203 *                        wcsprm::flag should be set to -1 when wcs is
00204 *                        initialized for the first time (memory leaks may
00205 *                        result if it had already been initialized).
00206 *
00207 * Given:
00208 *   npvmax     int       The number of PVi_ma keywords to allocate space for.
00209 *                        If set to -1, the value of the global variable NPVMAX
00210 *                        will be used.  This is potentially thread-unsafe if
00211 *                        wcsnpv() is being used dynamically to alter its value.
00212 *
00213 *   npsmax     int       The number of PSi_ma keywords to allocate space for.
00214 *                        If set to -1, the value of the global variable NPSMAX
00215 *                        will be used.  This is potentially thread-unsafe if
00216 *                        wcsnps() is being used dynamically to alter its value.
00217 *
00218 *   ndpmax     int       The number of DPja or DQia keywords to allocate space
00219 *                        for.  If set to -1, the value of the global variable
00220 *                        NDPMAX will be used.  This is potentially
00221 *                        thread-unsafe if disndp() is being used dynamically to
00222 *                        alter its value.
00223 *
00224 * Function return value:
00225 *              int       Status return value:
00226 *                          0: Success.
00227 *                          1: Null wcsprm pointer passed.
00228 *                          2: Memory allocation failed.
00229 *
00230 *                        For returns > 1, a detailed error message is set in
00231 *                        wcsprm::err if enabled, see wcserr_enable().
00232 *
00233 *
```

```
00234 * wcsauxi() - Default constructor for the auxprm struct
00235 * ---------------------------------------------------
00236 * wcsauxi() optionally allocates memory for an auxprm struct, attaches it to
00237 * wcsprm, and sets all members of the struct to default values.
00238 *
00239 * Given:
00240 *   alloc     int       If true, allocate memory unconditionally for the
00241 *                       auxprm struct.
00242 *
00243 *                       If false, it is assumed that wcsprm::aux has already
00244 *                       been set to point to an auxprm struct, in which case
00245 *                       the user is responsible for managing that memory.
00246 *                       However, if wcsprm::aux is a null pointer, memory will
00247 *                       be allocated regardless.  (In other words, setting
00248 *                       alloc true saves having to initalize the pointer to
00249 *                       zero.)
00250 *
00251 * Given and returned:
00252 *   wcs       struct wcsprm*
00253 *                       Coordinate transformation parameters.
00254 *
00255 * Function return value:
00256 *             int       Status return value:
00257 *                         0: Success.
00258 *                         1: Null wcsprm pointer passed.
00259 *                         2: Memory allocation failed.
00260 *
00261 *
00262 * wcssub() - Subimage extraction routine for the wcsprm struct
00263 * ------------------------------------------------------------
00264 * wcssub() extracts the coordinate description for a subimage from a wcsprm
00265 * struct.  It does a deep copy, using wcsinit() to allocate memory for its
00266 * arrays if required.  Only the "information to be provided" part of the
00267 * struct is extracted.  Consequently, wcsset() need not have been, and won't
00268 * be invoked on the struct from which the subimage is extracted.  A call to
00269 * wcsset() is required to set up the subimage struct.
00270 *
00271 * The world coordinate system of the subimage must be separable in the sense
00272 * that the world coordinates at any point in the subimage must depend only on
00273 * the pixel coordinates of the axes extracted.  In practice, this means that
00274 * the linear transformation matrix of the original image must not contain
00275 * non-zero off-diagonal terms that associate any of the subimage axes with any
00276 * of the non-subimage axes.  Likewise, if any distortions are associated with
00277 * the subimage axes, they must not depend on any of the axes that are not
00278 * being extracted.
00279 *
00280 * Note that while the required elements of the tabprm array are extracted, the
00281 * wtbarr array is not.  (Thus it is not appropriate to call wcssub() after
00282 * wcstab() but before filling the tabprm structs - refer to wcshdr.h.)
00283 *
00284 * wcssub() can also add axes to a wcsprm struct.  The new axes will be created
00285 * using the defaults set by wcsinit() which produce a simple, unnamed, linear
00286 * axis with world coordinate equal to the pixel coordinate.  These default
00287 * values can be changed afterwards, before invoking wcsset().
00288 *
00289 * Given:
00290 *   alloc     int       If true, allocate memory for the crpix, etc. arrays in
00291 *                       the destination.  Otherwise, it is assumed that
00292 *                       pointers to these arrays have been set by the user
00293 *                       except if they are null pointers in which case memory
00294 *                       will be allocated for them regardless.
00295 *
00296 *   wcssrc    const struct wcsprm*
00297 *                       Struct to extract from.
00298 *
00299 * Given and returned:
00300 *   nsub      int*
00301 *   axes      int[]     Vector of length *nsub containing the image axis
00302 *                       numbers (1-relative) to extract.  Order is
00303 *                       significant; axes[0] is the axis number of the input
00304 *                       image that corresponds to the first axis in the
00305 *                       subimage, etc.
00306 *
00307 *                       Use an axis number of 0 to create a new axis using
00308 *                       the defaults set by wcsinit().  They can be changed
00309 *                       later.
00310 *
00311 *                       nsub (the pointer) may be set to zero, and so also may
00312 *                       *nsub, which is interpreted to mean all axes in the
00313 *                       input image; the number of axes will be returned if
00314 *                       nsub != 0x0.  axes itself (the pointer) may be set to
00315 *                       zero to indicate the first *nsub axes in their
00316 *                       original order.
00317 *
00318 *                       Set both nsub (or *nsub) and axes to zero to do a deep
00319 *                       copy of one wcsprm struct to another.
00320 *
```

```
00321 *                       Subimage extraction by coordinate axis type may be
00322 *                       done by setting the elements of axes[] to the
00323 *                       following special preprocessor macro values:
00324 *
00325 *                         WCSSUB_LONGITUDE: Celestial longitude.
00326 *                         WCSSUB_LATITUDE:  Celestial latitude.
00327 *                         WCSSUB_CUBEFACE:  Quadcube CUBEFACE axis.
00328 *                         WCSSUB_SPECTRAL:  Spectral axis.
00329 *                         WCSSUB_STOKES:    Stokes axis.
00330 *                         WCSSUB_TIME:      Time axis.
00331 *
00332 *                       Refer to the notes (below) for further usage examples.
00333 *
00334 *                       On return, *nsub will be set to the number of axes in
00335 *                       the subimage; this may be zero if there were no axes
00336 *                       of the required type(s) (in which case no memory will
00337 *                       be allocated).  axes[] will contain the axis numbers
00338 *                       that were extracted, or 0 for newly created axes.  The
00339 *                       vector length must be sufficient to contain all axis
00340 *                       numbers.  No checks are performed to verify that the
00341 *                       coordinate axes are consistent, this is done by
00342 *                       wcsset().
00343 *
00344 *   wcsdst    struct wcsprm*
00345 *                       Struct describing the subimage.  wcsprm::flag should
00346 *                       be set to -1 if wcsdst was not previously initialized
00347 *                       (memory leaks may result if it was previously
00348 *                       initialized).
00349 *
00350 * Function return value:
00351 *             int       Status return value:
00352 *                         0: Success.
00353 *                         1: Null wcsprm pointer passed.
00354 *                         2: Memory allocation failed.
00355 *                        12: Invalid subimage specification.
00356 *                        13: Non-separable subimage coordinate system.
00357 *
00358 *                       For returns > 1, a detailed error message is set in
00359 *                       wcsprm::err if enabled, see wcserr_enable().
00360 *
00361 * Notes:
00362 *   1: Combinations of subimage axes of particular types may be extracted in
00363 *      the same order as they occur in the input image by combining
00364 *      preprocessor codes, for example
00365 *
00366 =        *nsub = 1;
00367 =        axes[0] = WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_SPECTRAL;
00368 *
00369 *      would extract the longitude, latitude, and spectral axes in the same
00370 *      order as the input image.  If one of each were present, *nsub = 3 would
00371 *      be returned.
00372 *
00373 *      For convenience, WCSSUB_CELESTIAL is defined as the combination
00374 *      WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_CUBEFACE.
00375 *
00376 *      The codes may also be negated to extract all but the types specified,
00377 *      for example
00378 *
00379 =        *nsub = 4;
00380 =        axes[0] = WCSSUB_LONGITUDE;
00381 =        axes[1] = WCSSUB_LATITUDE;
00382 =        axes[2] = WCSSUB_CUBEFACE;
00383 =        axes[3] = -(WCSSUB_SPECTRAL | WCSSUB_STOKES);
00384 *
00385 *      The last of these specifies all axis types other than spectral or
00386 *      Stokes.  Extraction is done in the order specified by axes[] a
00387 *      longitude axis (if present) would be extracted first (via axes[0]) and
00388 *      not subsequently (via axes[3]).  Likewise for the latitude and cubeface
00389 *      axes in this example.
00390 *
00391 *      From the foregoing, it is apparent that the value of *nsub returned may
00392 *      be less than or greater than that given.  However, it will never exceed
00393 *      the number of axes in the input image (plus the number of newly-created
00394 *      axes if any were specified on input).
00395 *
00396 *
00397 * wcscompare() - Compare two wcsprm structs for equality
00398 * ------------------------------------------------------
00399 * wcscompare() compares two wcsprm structs for equality.
00400 *
00401 * Given:
00402 *   cmp       int       A bit field controlling the strictness of the
00403 *                       comparison.  When 0, all fields must be identical.
00404 *
00405 *                       The following constants may be or'ed together to
00406 *                       relax the comparison:
00407 *                         WCSCOMPARE_ANCILLARY: Ignore ancillary keywords
```

```
00408 *                           that don't change the WCS transformation, such
00409 *                           as DATE-OBS or EQUINOX.
00410 *                         WCSCOMPARE_TILING: Ignore integral differences in
00411 *                           CRPIXja.  This is the 'tiling' condition, where
00412 *                           two WCSes cover different regions of the same
00413 *                           map projection and align on the same map grid.
00414 *                         WCSCOMPARE_CRPIX: Ignore any differences at all in
00415 *                           CRPIXja.  The two WCSes cover different regions
00416 *                           of the same map projection but may not align on
00417 *                           the same map grid.  Overrides WCSCOMPARE_TILING.
00418 *
00419 *   tol       double    Tolerance for comparison of floating-point values.
00420 *                       For example, for tol == 1e-6, all floating-point
00421 *                       values in the structs must be equal to the first 6
00422 *                       decimal places.  A value of 0 implies exact equality.
00423 *
00424 *   wcs1      const struct wcsprm*
00425 *                       The first wcsprm struct to compare.
00426 *
00427 *   wcs2      const struct wcsprm*
00428 *                       The second wcsprm struct to compare.
00429 *
00430 * Returned:
00431 *   equal     int*      Non-zero when the given structs are equal.
00432 *
00433 * Function return value:
00434 *             int       Status return value:
00435 *                         0: Success.
00436 *                         1: Null pointer passed.
00437 *
00438 *
00439 * wcscopy() macro - Copy routine for the wcsprm struct
00440 * ----------------------------------------------------
00441 * wcscopy() does a deep copy of one wcsprm struct to another.  As of
00442 * WCSLIB 3.6, it is implemented as a preprocessor macro that invokes
00443 * wcssub() with the nsub and axes pointers both set to zero.
00444 *
00445 *
00446 * wcsfree() - Destructor for the wcsprm struct
00447 * --------------------------------------------
00448 * wcsfree() frees memory allocated for the wcsprm arrays by wcsinit() and/or
00449 * wcsset().  wcsinit() records the memory it allocates and wcsfree() will only
00450 * attempt to free this.
00451 *
00452 * PLEASE NOTE: wcsfree() must not be invoked on a wcsprm struct that was not
00453 * initialized by wcsinit().
00454 *
00455 * Given and returned:
00456 *   wcs       struct wcsprm*
00457 *                       Coordinate transformation parameters.
00458 *
00459 * Function return value:
00460 *             int       Status return value:
00461 *                         0: Success.
00462 *                         1: Null wcsprm pointer passed.
00463 *
00464 *
00465 * wcstrim() - Free unused arrays in the wcsprm struct
00466 * ---------------------------------------------------
00467 * wcstrim() frees memory allocated by wcsinit() for arrays in the wcsprm
00468 * struct that remains unused after it has been set up by wcsset().
00469 *
00470 * The free'd array members are associated with FITS WCS keyrecords that are
00471 * rarely used and usually just bloat the struct: wcsprm::crota, wcsprm::colax,
00472 * wcsprm::cname, wcsprm::crder, wcsprm::csyer, wcsprm::czphs, and
00473 * wcsprm::cperi.  If unused, wcsprm::pv, wcsprm::ps, and wcsprm::cd are also
00474 * freed.
00475 *
00476 * Once these arrays have been freed, a test such as
00477 =
00478 =       if (!undefined(wcs->cname[i])) {...}
00479 =
00480 * must be protected as follows
00481 =
00482 =       if (wcs->cname && !undefined(wcs->cname[i])) {...}
00483 =
00484 * In addition, if wcsprm::npv is non-zero but less than wcsprm::npvmax, then
00485 * the unused space in wcsprm::pv will be recovered (using realloc()).
00486 * Likewise for wcsprm::ps.
00487 *
00488 * Given and returned:
00489 *   wcs       struct wcsprm*
00490 *                       Coordinate transformation parameters.
00491 *
00492 * Function return value:
00493 *             int       Status return value:
00494 *                         0: Success.
```

```
00495 *                         1: Null wcsprm pointer passed.
00496 *                        14: wcsprm struct is unset.
00497 *
00498 *
00499 * wcssize() - Compute the size of a wcsprm struct
00500 * ----------------------------------------------
00501 * wcssize() computes the full size of a wcsprm struct, including allocated
00502 * memory.
00503 *
00504 * Given:
00505 *   wcs       const struct wcsprm*
00506 *                       Coordinate transformation parameters.
00507 *
00508 *                       If NULL, the base size of the struct and the allocated
00509 *                       size are both set to zero.
00510 *
00511 * Returned:
00512 *   sizes     int[2]    The first element is the base size of the struct as
00513 *                       returned by sizeof(struct wcsprm).  The second element
00514 *                       is the total allocated size, in bytes, assuming that
00515 *                       the allocation was done by wcsini().  This figure
00516 *                       includes memory allocated for members of constituent
00517 *                       structs, such as wcsprm::lin.
00518 *
00519 *                       It is not an error for the struct not to have been set
00520 *                       up via wcsset(), which normally results in additional
00521 *                       memory allocation.
00522 *
00523 * Function return value:
00524 *             int       Status return value:
00525 *                         0: Success.
00526 *
00527 *
00528 * auxsize() - Compute the size of a auxprm struct
00529 * -----------------------------------------------
00530 * auxsize() computes the full size of an auxprm struct, including allocated
00531 * memory.
00532 *
00533 * Given:
00534 *   aux       const struct auxprm*
00535 *                       Auxiliary coordinate information.
00536 *
00537 *                       If NULL, the base size of the struct and the allocated
00538 *                       size are both set to zero.
00539 *
00540 * Returned:
00541 *   sizes     int[2]    The first element is the base size of the struct as
00542 *                       returned by sizeof(struct auxprm).  The second element
00543 *                       is the total allocated size, in bytes, currently zero.
00544 *
00545 * Function return value:
00546 *             int       Status return value:
00547 *                         0: Success.
00548 *
00549 *
00550 * wcsprt() - Print routine for the wcsprm struct
00551 * ----------------------------------------------
00552 * wcsprt() prints the contents of a wcsprm struct using wcsprintf().  Mainly
00553 * intended for diagnostic purposes.
00554 *
00555 * Given:
00556 *   wcs       const struct wcsprm*
00557 *                       Coordinate transformation parameters.
00558 *
00559 * Function return value:
00560 *             int       Status return value:
00561 *                         0: Success.
00562 *                         1: Null wcsprm pointer passed.
00563 *
00564 *
00565 * wcsperr() - Print error messages from a wcsprm struct
00566 * -----------------------------------------------------
00567 * wcsperr() prints the error message(s), if any, stored in a wcsprm struct,
00568 * and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains.
00569 * If there are no errors then nothing is printed.  It uses wcserr_prt(), q.v.
00570 *
00571 * Given:
00572 *   wcs       const struct wcsprm*
00573 *                       Coordinate transformation parameters.
00574 *
00575 *   prefix    const char *
00576 *                       If non-NULL, each output line will be prefixed with
00577 *                       this string.
00578 *
00579 * Function return value:
00580 *             int       Status return value:
00581 *                         0: Success.
```

```
00582 *                         1: Null wcsprm pointer passed.
00583 *
00584 *
00585 * wcsbchk() - Enable/disable bounds checking
00586 * -----------------------------------------
00587 * wcsbchk() is used to control bounds checking in the projection routines.
00588 * Note that wcsset() always enables bounds checking.  wcsbchk() will invoke
00589 * wcsset() on the wcsprm struct beforehand if necessary.
00590 *
00591 * Given and returned:
00592 *   wcs       struct wcsprm*
00593 *                       Coordinate transformation parameters.
00594 *
00595 * Given:
00596 *   bounds    int       If bounds&1 then enable strict bounds checking for the
00597 *                       spherical-to-Cartesian (s2x) transformation for the
00598 *                       AZP, SZP, TAN, SIN, ZPN, and COP projections.
00599 *
00600 *                       If bounds&2 then enable strict bounds checking for the
00601 *                       Cartesian-to-spherical (x2s) transformation for the
00602 *                       HPX and XPH projections.
00603 *
00604 *                       If bounds&4 then enable bounds checking on the native
00605 *                       coordinates returned by the Cartesian-to-spherical
00606 *                       (x2s) transformations using prjchk().
00607 *
00608 *                       Zero it to disable all checking.
00609 *
00610 * Function return value:
00611 *             int       Status return value:
00612 *                         0: Success.
00613 *                         1: Null wcsprm pointer passed.
00614 *
00615 *
00616 * wcsset() - Setup routine for the wcsprm struct
00617 * ----------------------------------------------
00618 * wcsset() sets up a wcsprm struct according to information supplied within
00619 * it (refer to the description of the wcsprm struct).
00620 *
00621 * wcsset() recognizes the NCP projection and converts it to the equivalent SIN
00622 * projection and likewise translates GLS into SFL.  It also translates the
00623 * AIPS spectral types ('FREQ-LSR', 'FELO-HEL', etc.), possibly changing the
00624 * input header keywords wcsprm::ctype and/or wcsprm::specsys if necessary.
00625 *
00626 * Note that this routine need not be called directly; it will be invoked by
00627 * wcsp2s() and wcss2p() if the wcsprm::flag is anything other than a
00628 * predefined magic value.
00629 *
00630 * Given and returned:
00631 *   wcs       struct wcsprm*
00632 *                       Coordinate transformation parameters.
00633 *
00634 * Function return value:
00635 *             int       Status return value:
00636 *                         0: Success.
00637 *                         1: Null wcsprm pointer passed.
00638 *                         2: Memory allocation failed.
00639 *                         3: Linear transformation matrix is singular.
00640 *                         4: Inconsistent or unrecognized coordinate axis
00641 *                            types.
00642 *                         5: Invalid parameter value.
00643 *                         6: Invalid coordinate transformation parameters.
00644 *                         7: Ill-conditioned coordinate transformation
00645 *                            parameters.
00646 *
00647 *                       For returns > 1, a detailed error message is set in
00648 *                       wcsprm::err if enabled, see wcserr_enable().
00649 *
00650 * Notes:
00651 *   1: wcsset() always enables strict bounds checking in the projection
00652 *      routines (via a call to prjini()).  Use wcsbchk() to modify
00653 *      bounds-checking after wcsset() is invoked.
00654 *
00655 *
00656 * wcsp2s() - Pixel-to-world transformation
00657 * ---------------------------------------
00658 * wcsp2s() transforms pixel coordinates to world coordinates.
00659 *
00660 * Given and returned:
00661 *   wcs       struct wcsprm*
00662 *                       Coordinate transformation parameters.
00663 *
00664 * Given:
00665 *   ncoord,
00666 *   nelem     int       The number of coordinates, each of vector length
00667 *                       nelem but containing wcs.naxis coordinate elements.
00668 *                       Thus nelem must equal or exceed the value of the
```

```
00669 *                       NAXIS keyword unless ncoord == 1, in which case nelem
00670 *                       is not used.
00671 *
00672 *   pixcrd    const double[ncoord][nelem]
00673 *                       Array of pixel coordinates.
00674 *
00675 * Returned:
00676 *   imgcrd    double[ncoord][nelem]
00677 *                       Array of intermediate world coordinates.  For
00678 *                       celestial axes, imgcrd[][wcs.lng] and
00679 *                       imgcrd[][wcs.lat] are the projected x-, and
00680 *                       y-coordinates in pseudo "degrees".  For spectral
00681 *                       axes, imgcrd[][wcs.spec] is the intermediate spectral
00682 *                       coordinate, in SI units.  For time axes,
00683 *                       imgcrd[][wcs.time] is the intermediate time
00684 *                       coordinate.
00685 *
00686 *   phi,theta double[ncoord]
00687 *                       Longitude and latitude in the native coordinate system
00688 *                       of the projection [deg].
00689 *
00690 *   world     double[ncoord][nelem]
00691 *                       Array of world coordinates.  For celestial axes,
00692 *                       world[][wcs.lng] and world[][wcs.lat] are the
00693 *                       celestial longitude and latitude [deg].  For spectral
00694 *                       axes, world[][wcs.spec] is the spectral coordinate, in
00695 *                       SI units.  For time axes, world[][wcs.time] is the
00696 *                       time coordinate.
00697 *
00698 *   stat      int[ncoord]
00699 *                       Status return value for each coordinate:
00700 *                         0: Success.
00701 *                        1+: A bit mask indicating invalid pixel coordinate
00702 *                            element(s).
00703 *
00704 * Function return value:
00705 *             int       Status return value:
00706 *                         0: Success.
00707 *                         1: Null wcsprm pointer passed.
00708 *                         2: Memory allocation failed.
00709 *                         3: Linear transformation matrix is singular.
00710 *                         4: Inconsistent or unrecognized coordinate axis
00711 *                            types.
00712 *                         5: Invalid parameter value.
00713 *                         6: Invalid coordinate transformation parameters.
00714 *                         7: Ill-conditioned coordinate transformation
00715 *                            parameters.
00716 *                         8: One or more of the pixel coordinates were
00717 *                            invalid, as indicated by the stat vector.
00718 *
00719 *                       For returns > 1, a detailed error message is set in
00720 *                       wcsprm::err if enabled, see wcserr_enable().
00721 *
00722 *
00723 * wcss2p() - World-to-pixel transformation
00724 * ----------------------------------------
00725 * wcss2p() transforms world coordinates to pixel coordinates.
00726 *
00727 * Given and returned:
00728 *   wcs       struct wcsprm*
00729 *                       Coordinate transformation parameters.
00730 *
00731 * Given:
00732 *   ncoord,
00733 *   nelem     int       The number of coordinates, each of vector length nelem
00734 *                       but containing wcs.naxis coordinate elements.  Thus
00735 *                       nelem must equal or exceed the value of the NAXIS
00736 *                       keyword unless ncoord == 1, in which case nelem is not
00737 *                       used.
00738 *
00739 *   world     const double[ncoord][nelem]
00740 *                       Array of world coordinates.  For celestial axes,
00741 *                       world[][wcs.lng] and world[][wcs.lat] are the
00742 *                       celestial longitude and latitude [deg]. For spectral
00743 *                       axes, world[][wcs.spec] is the spectral coordinate, in
00744 *                       SI units.  For time axes, world[][wcs.time] is the
00745 *                       time coordinate.
00746 *
00747 * Returned:
00748 *   phi,theta double[ncoord]
00749 *                       Longitude and latitude in the native coordinate
00750 *                       system of the projection [deg].
00751 *
00752 *   imgcrd    double[ncoord][nelem]
00753 *                       Array of intermediate world coordinates.  For
00754 *                       celestial axes, imgcrd[][wcs.lng] and
00755 *                       imgcrd[][wcs.lat] are the projected x-, and
```

```
00756 *                       y-coordinates in pseudo "degrees".  For quadcube
00757 *                       projections with a CUBEFACE axis the face number is
00758 *                       also returned in imgcrd[][wcs.cubeface].  For
00759 *                       spectral axes, imgcrd[][wcs.spec] is the intermediate
00760 *                       spectral coordinate, in SI units.  For time axes,
00761 *                       imgcrd[][wcs.time] is the intermediate time
00762 *                       coordinate.
00763 *
00764 *   pixcrd    double[ncoord][nelem]
00765 *                       Array of pixel coordinates.
00766 *
00767 *   stat      int[ncoord]
00768 *                       Status return value for each coordinate:
00769 *                         0: Success.
00770 *                        1+: A bit mask indicating invalid world coordinate
00771 *                            element(s).
00772 *
00773 * Function return value:
00774 *             int       Status return value:
00775 *                         0: Success.
00776 *                         1: Null wcsprm pointer passed.
00777 *                         2: Memory allocation failed.
00778 *                         3: Linear transformation matrix is singular.
00779 *                         4: Inconsistent or unrecognized coordinate axis
00780 *                            types.
00781 *                         5: Invalid parameter value.
00782 *                         6: Invalid coordinate transformation parameters.
00783 *                         7: Ill-conditioned coordinate transformation
00784 *                            parameters.
00785 *                         9: One or more of the world coordinates were
00786 *                            invalid, as indicated by the stat vector.
00787 *
00788 *                       For returns > 1, a detailed error message is set in
00789 *                       wcsprm::err if enabled, see wcserr_enable().
00790 *
00791 *
00792 * wcsmix() - Hybrid coordinate transformation
00793 * -------------------------------------------
00794 * wcsmix(), given either the celestial longitude or latitude plus an element
00795 * of the pixel coordinate, solves for the remaining elements by iterating on
00796 * the unknown celestial coordinate element using wcss2p().  Refer also to the
00797 * notes below.
00798 *
00799 * Given and returned:
00800 *   wcs       struct wcsprm*
00801 *                       Indices for the celestial coordinates obtained
00802 *                       by parsing the wcsprm::ctype[].
00803 *
00804 * Given:
00805 *   mixpix    int       Which element of the pixel coordinate is given.
00806 *
00807 *   mixcel    int       Which element of the celestial coordinate is given:
00808 *                         1: Celestial longitude is given in
00809 *                            world[wcs.lng], latitude returned in
00810 *                            world[wcs.lat].
00811 *                         2: Celestial latitude is given in
00812 *                            world[wcs.lat], longitude returned in
00813 *                            world[wcs.lng].
00814 *
00815 *   vspan     const double[2]
00816 *                       Solution interval for the celestial coordinate [deg].
00817 *                       The ordering of the two limits is irrelevant.
00818 *                       Longitude ranges may be specified with any convenient
00819 *                       normalization, for example [-120,+120] is the same as
00820 *                       [240,480], except that the solution will be returned
00821 *                       with the same normalization, i.e. lie within the
00822 *                       interval specified.
00823 *
00824 *   vstep     const double
00825 *                       Step size for solution search [deg].  If zero, a
00826 *                       sensible, although perhaps non-optimal default will be
00827 *                       used.
00828 *
00829 *   viter     int       If a solution is not found then the step size will be
00830 *                       halved and the search recommenced.  viter controls how
00831 *                       many times the step size is halved.  The allowed range
00832 *                       is 5 - 10.
00833 *
00834 * Given and returned:
00835 *   world     double[naxis]
00836 *                       World coordinate elements.  world[wcs.lng] and
00837 *                       world[wcs.lat] are the celestial longitude and
00838 *                       latitude [deg].  Which is given and which returned
00839 *                       depends on the value of mixcel.  All other elements
00840 *                       are given.
00841 *
00842 * Returned:
```

```
00843 *   phi,theta double[naxis]
00844 *                       Longitude and latitude in the native coordinate
00845 *                       system of the projection [deg].
00846 *
00847 *   imgcrd    double[naxis]
00848 *                       Image coordinate elements.  imgcrd[wcs.lng] and
00849 *                       imgcrd[wcs.lat] are the projected x-, and
00850 *                       y-coordinates in pseudo "degrees".
00851 *
00852 * Given and returned:
00853 *   pixcrd    double[naxis]
00854 *                       Pixel coordinate.  The element indicated by mixpix is
00855 *                       given and the remaining elements are returned.
00856 *
00857 * Function return value:
00858 *             int       Status return value:
00859 *                         0: Success.
00860 *                         1: Null wcsprm pointer passed.
00861 *                         2: Memory allocation failed.
00862 *                         3: Linear transformation matrix is singular.
00863 *                         4: Inconsistent or unrecognized coordinate axis
00864 *                            types.
00865 *                         5: Invalid parameter value.
00866 *                         6: Invalid coordinate transformation parameters.
00867 *                         7: Ill-conditioned coordinate transformation
00868 *                            parameters.
00869 *                        10: Invalid world coordinate.
00870 *                        11: No solution found in the specified interval.
00871 *
00872 *                       For returns > 1, a detailed error message is set in
00873 *                       wcsprm::err if enabled, see wcserr_enable().
00874 *
00875 * Notes:
00876 *   1: Initially the specified solution interval is checked to see if it's a
00877 *      "crossing" interval.  If it isn't, a search is made for a crossing
00878 *      solution by iterating on the unknown celestial coordinate starting at
00879 *      the upper limit of the solution interval and decrementing by the
00880 *      specified step size.  A crossing is indicated if the trial value of the
00881 *      pixel coordinate steps through the value specified.  If a crossing
00882 *      interval is found then the solution is determined by a modified form of
00883 *      "regula falsi" division of the crossing interval.  If no crossing
00884 *      interval was found within the specified solution interval then a search
00885 *      is made for a "non-crossing" solution as may arise from a point of
00886 *      tangency.  The process is complicated by having to make allowance for
00887 *      the discontinuities that occur in all map projections.
00888 *
00889 *      Once one solution has been determined others may be found by subsequent
00890 *      invokations of wcsmix() with suitably restricted solution intervals.
00891 *
00892 *      Note the circumstance that arises when the solution point lies at a
00893 *      native pole of a projection in which the pole is represented as a
00894 *      finite curve, for example the zenithals and conics.  In such cases two
00895 *      or more valid solutions may exist but wcsmix() only ever returns one.
00896 *
00897 *      Because of its generality wcsmix() is very compute-intensive.  For
00898 *      compute-limited applications more efficient special-case solvers could
00899 *      be written for simple projections, for example non-oblique cylindrical
00900 *      projections.
00901 *
00902 *
00903 * wcsccs() - Change celestial coordinate system
00904 * ---------------------------------------------
00905 * wcsccs() changes the celestial coordinate system of a wcsprm struct.  For
00906 * example, from equatorial to galactic coordinates.
00907 *
00908 * Parameters that define the spherical coordinate transformation, essentially
00909 * being three Euler angles, must be provided.  Thereby wcsccs() does not need
00910 * prior knowledge of specific celestial coordinate systems.  It also has the
00911 * advantage of making it completely general.
00912 *
00913 * Auxiliary members of the wcsprm struct relating to equatorial celestial
00914 * coordinate systems may also be changed.
00915 *
00916 * Only orthodox spherical coordinate systems are supported.  That is, they
00917 * must be right-handed, with latitude increasing from zero at the equator to
00918 * +90 degrees at the pole.  This precludes systems such as aziumuth and zenith
00919 * distance, which, however, could be handled as negative azimuth and
00920 * elevation.
00921 *
00922 * PLEASE NOTE: Information in the wcsprm struct relating to the original
00923 * coordinate system will be overwritten and therefore lost.  If this is
00924 * undesirable, invoke wcsccs() on a copy of the struct made with wcssub().
00925 * The wcsprm struct is reset on return with an explicit call to wcsset().
00926 *
00927 * Given and returned:
00928 *   wcs       struct wcsprm*
00929 *                       Coordinate transformation parameters.  Particular
```

```
00930 *                       "values to be given" elements of the wcsprm struct
00931 *                       are modified.
00932 *
00933 * Given:
00934 *   lng2p1,
00935 *   lat2p1    double    Longitude and latitude in the new celestial coordinate
00936 *                       system of the pole (i.e. latitude +90) of the original
00937 *                       system [deg].  See notes 1 and 2 below.
00938 *
00939 *   lng1p2    double    Longitude in the original celestial coordinate system
00940 *                       of the pole (i.e. latitude +90) of the new system
00941 *                       [deg].  See note 1 below.
00942 *
00943 *   clng,clat const char*
00944 *                       Longitude and latitude identifiers of the new CTYPEia
00945 *                       celestial axis codes, without trailing dashes.  For
00946 *                       example, "RA" and "DEC" or "GLON" and "GLAT".  Up to
00947 *                       four characters are used, longer strings need not be
00948 *                       null-terminated.
00949 *
00950 *   radesys   const char*
00951 *                       Used when transforming to equatorial coordinates,
00952 *                       identified by clng == "RA" and clat = "DEC".  May be
00953 *                       set to the null pointer to preserve the current value.
00954 *                       Up to 71 characters are used, longer strings need not
00955 *                       be null-terminated.
00956 *
00957 *                       If the new coordinate system is anything other than
00958 *                       equatorial, then wcsprm::radesys will be cleared.
00959 *
00960 *   equinox   double    Used when transforming to equatorial coordinates.  May
00961 *                       be set to zero to preserve the current value.
00962 *
00963 *                       If the new coordinate system is not equatorial, then
00964 *                       wcsprm::equinox will be marked as undefined.
00965 *
00966 *   alt       const char*
00967 *                       Character code for alternate coordinate descriptions
00968 *                       (i.e. the 'a' in keyword names such as CTYPEia).  This
00969 *                       is blank for the primary coordinate description, or
00970 *                       one of the 26 upper-case letters, A-Z.  May be set to
00971 *                       the null pointer, or null string if no change is
00972 *                       required.
00973 *
00974 * Function return value:
00975 *             int       Status return value:
00976 *                         0: Success.
00977 *                         1: Null wcsprm pointer passed.
00978 *                        12: Invalid subimage specification (no celestial
00979 *                            axes).
00980 *
00981 * Notes:
00982 *   1: Follows the prescription given in WCS Paper II, Sect. 2.7 for changing
00983 *      celestial coordinates.
00984 *
00985 *      The implementation takes account of indeterminacies that arise in that
00986 *      prescription in the particular cases where one of the poles of the new
00987 *      system is at the fiducial point, or one of them is at the native pole.
00988 *
00989 *   2: If lat2p1 == +90, i.e. where the poles of the two coordinate systems
00990 *      coincide, then the spherical coordinate transformation becomes a simple
00991 *      change in origin of longitude given by
00992 *      lng2 = lng1 + (lng2p1 - lng1p2 - 180), and lat2 = lat1, where
00993 *      (lng2,lat2) are coordinates in the new system, and (lng1,lat1) are
00994 *      coordinates in the original system.
00995 *
00996 *      Likewise, if lat2p1 == -90, then lng2 = -lng1 + (lng2p1 + lng1p2), and
00997 *      lat2 = -lat1.
00998 *
00999 *   3: For example, if the original coordinate system is B1950 equatorial and
01000 *      the desired new coordinate system is galactic, then
01001 *
01002 *      - (lng2p1,lat2p1) are the galactic coordinates of the B1950 celestial
01003 *        pole, defined by the IAU to be (123.0,+27.4), and lng1p2 is the B1950
01004 *        right ascension of the galactic pole, defined as 192.25.  Clearly
01005 *        these coordinates are fixed for a particular coordinate
01006 *        transformation.
01007 *
01008 *      - (clng,clat) would be 'GLON' and 'GLAT', these being the FITS standard
01009 *        identifiers for galactic coordinates.
01010 *
01011 *      - Since the new coordinate system is not equatorial, wcsprm::radesys
01012 *        and wcsprm::equinox will be cleared.
01013 *
01014 *   4. The coordinates required for some common transformations (obtained from
01015 *      https://ned.ipac.caltech.edu/coordinate_calculator) are as follows:
01016 *
```

```
01017 =      (123.0000,+27.4000) galactic coordinates of B1950 celestial pole,
01018 =      (192.2500,+27.4000) B1950 equatorial coordinates of galactic pole.
01019 *
01020 =      (122.9319,+27.1283) galactic coordinates of J2000 celestial pole,
01021 =      (192.8595,+27.1283) J2000 equatorial coordinates of galactic pole.
01022 *
01023 =      (359.6774,+89.7217) B1950 equatorial coordinates of J2000 pole,
01024 =      (180.3162,+89.7217) J2000 equatorial coordinates of B1950 pole.
01025 *
01026 =      (270.0000,+66.5542) B1950 equatorial coordinates of B1950 ecliptic pole,
01027 =      ( 90.0000,+66.5542) B1950 ecliptic coordinates of B1950 celestial pole.
01028 *
01029 =      (270.0000,+66.5607) J2000 equatorial coordinates of J2000 ecliptic pole,
01030 =      ( 90.0000,+66.5607) J2000 ecliptic coordinates of J2000 celestial pole.
01031 *
01032 =      ( 26.7315,+15.6441) supergalactic coordinates of B1950 celestial pole,
01033 =      (283.1894,+15.6441) B1950 equatorial coordinates of supergalactic pole.
01034 *
01035 =      ( 26.4505,+15.7089) supergalactic coordinates of J2000 celestial pole,
01036 =      (283.7542,+15.7089) J2000 equatorial coordinates of supergalactic pole.
01037 *
01038 *
01039 * wcssptr() - Spectral axis translation
01040 * ------------------------------------
01041 * wcssptr() translates the spectral axis in a wcsprm struct.  For example, a
01042 * 'FREQ' axis may be translated into 'ZOPT-F2W' and vice versa.
01043 *
01044 * PLEASE NOTE: Information in the wcsprm struct relating to the original
01045 * coordinate system will be overwritten and therefore lost.  If this is
01046 * undesirable, invoke wcssptr() on a copy of the struct made with wcssub().
01047 * The wcsprm struct is reset on return with an explicit call to wcsset().
01048 *
01049 * Given and returned:
01050 *   wcs       struct wcsprm*
01051 *                       Coordinate transformation parameters.
01052 *
01053 *   i         int*      Index of the spectral axis (0-relative).  If given < 0
01054 *                       it will be set to the first spectral axis identified
01055 *                       from the ctype[] keyvalues in the wcsprm struct.
01056 *
01057 *   ctype     char[9]   Desired spectral CTYPEia.  Wildcarding may be used as
01058 *                       for the ctypeS2 argument to spctrn() as described in
01059 *                       the prologue of spc.h, i.e. if the final three
01060 *                       characters are specified as "???", or if just the
01061 *                       eighth character is specified as '?', the correct
01062 *                       algorithm code will be substituted and returned.
01063 *
01064 * Function return value:
01065 *             int       Status return value:
01066 *                         0: Success.
01067 *                         1: Null wcsprm pointer passed.
01068 *                         2: Memory allocation failed.
01069 *                         3: Linear transformation matrix is singular.
01070 *                         4: Inconsistent or unrecognized coordinate axis
01071 *                            types.
01072 *                         5: Invalid parameter value.
01073 *                         6: Invalid coordinate transformation parameters.
01074 *                         7: Ill-conditioned coordinate transformation
01075 *                            parameters.
01076 *                        12: Invalid subimage specification (no spectral
01077 *                            axis).
01078 *
01079 *                       For returns > 1, a detailed error message is set in
01080 *                       wcsprm::err if enabled, see wcserr_enable().
01081 *
01082 *
01083 * wcslib_version() - WCSLIB version number
01084 * ---------------------------------------
01085 * wcslib_version() returns the WCSLIB version number.
01086 *
01087 * The major version number changes when the ABI changes or when the license
01088 * conditions change.  ABI changes typically result from a change to the
01089 * contents of one of the structs.  The major version number is used to
01090 * distinguish between incompatible versions of the sharable library.
01091 *
01092 * The minor version number changes with new functionality or bug fixes that do
01093 * not involve a change in the ABI.
01094 *
01095 * The auxiliary version number (which is often absent) signals changes to the
01096 * documentation, test suite, build procedures, or any other change that does
01097 * not affect the compiled library.
01098 *
01099 * Returned:
01100 *   vers[3]   int[3]    The broken-down version number:
01101 *                         0: Major version number.
01102 *                         1: Minor version number.
01103 *                         2: Auxiliary version number (zero if absent).
```

```
01104 *                      May be given as a null pointer if not required.
01105 *
01106 * Function return value:
01107 *             char*    A null-terminated, statically allocated string
01108 *                      containing the version number in the usual form, i.e.
01109 *                      "<major>.<minor>.<auxiliary>".
01110 *
01111 *
01112 * wcsprm struct - Coordinate transformation parameters
01113 * ----------------------------------------------------
01114 * The wcsprm struct contains information required to transform world
01115 * coordinates.  It consists of certain members that must be set by the user
01116 * ("given") and others that are set by the WCSLIB routines ("returned").
01117 * While the addresses of the arrays themselves may be set by wcsinit() if it
01118 * (optionally) allocates memory, their contents must be set by the user.
01119 *
01120 * Some parameters that are given are not actually required for transforming
01121 * coordinates.  These are described as "auxiliary"; the struct simply provides
01122 * a place to store them, though they may be used by wcshdo() in constructing a
01123 * FITS header from a wcsprm struct.  Some of the returned values are supplied
01124 * for informational purposes and others are for internal use only as
01125 * indicated.
01126 *
01127 * In practice, it is expected that a WCS parser would scan the FITS header to
01128 * determine the number of coordinate axes.  It would then use wcsinit() to
01129 * allocate memory for arrays in the wcsprm struct and set default values.
01130 * Then as it reread the header and identified each WCS keyrecord it would load
01131 * the value into the relevant wcsprm array element.  This is essentially what
01132 * wcspih() does - refer to the prologue of wcshdr.h.  As the final step,
01133 * wcsset() is invoked, either directly or indirectly, to set the derived
01134 * members of the wcsprm struct.  wcsset() strips off trailing blanks in all
01135 * string members and null-fills the character array.
01136 *
01137 *   int flag
01138 *     (Given and returned) This flag must be set to zero whenever any of the
01139 *     following wcsprm struct members are set or changed:
01140 *
01141 *       - wcsprm::naxis (q.v., not normally set by the user),
01142 *       - wcsprm::crpix,
01143 *       - wcsprm::pc,
01144 *       - wcsprm::cdelt,
01145 *       - wcsprm::crval,
01146 *       - wcsprm::cunit,
01147 *       - wcsprm::ctype,
01148 *       - wcsprm::lonpole,
01149 *       - wcsprm::latpole,
01150 *       - wcsprm::restfrq,
01151 *       - wcsprm::restwav,
01152 *       - wcsprm::npv,
01153 *       - wcsprm::pv,
01154 *       - wcsprm::nps,
01155 *       - wcsprm::ps,
01156 *       - wcsprm::cd,
01157 *       - wcsprm::crota,
01158 *       - wcsprm::altlin,
01159 *       - wcsprm::ntab,
01160 *       - wcsprm::nwtb,
01161 *       - wcsprm::tab,
01162 *       - wcsprm::wtb.
01163 *
01164 *     This signals the initialization routine, wcsset(), to recompute the
01165 *     returned members of the linprm, celprm, spcprm, and tabprm structs.
01166 *     wcsset() will reset flag to indicate that this has been done.
01167 *
01168 *     PLEASE NOTE: flag should be set to -1 when wcsinit() is called for the
01169 *     first time for a particular wcsprm struct in order to initialize memory
01170 *     management.  It must ONLY be used on the first initialization otherwise
01171 *     memory leaks may result.
01172 *
01173 *   int naxis
01174 *     (Given or returned) Number of pixel and world coordinate elements.
01175 *
01176 *     If wcsinit() is used to initialize the linprm struct (as would normally
01177 *     be the case) then it will set naxis from the value passed to it as a
01178 *     function argument.  The user should not subsequently modify it.
01179 *
01180 *   double *crpix
01181 *     (Given) Address of the first element of an array of double containing
01182 *     the coordinate reference pixel, CRPIXja.
01183 *
01184 *   double *pc
01185 *     (Given) Address of the first element of the PCi_ja (pixel coordinate)
01186 *     transformation matrix.  The expected order is
01187 *
01188 =       struct wcsprm wcs;
01189 =       wcs.pc = {PC1_1, PC1_2, PC2_1, PC2_2};
01190 *
```

```
01191 *     This may be constructed conveniently from a 2-D array via
01192 *
01193 =       double m[2][2] = {{PC1_1, PC1_2},
01194 =                         {PC2_1, PC2_2}};
01195 *
01196 *     which is equivalent to
01197 *
01198 =       double m[2][2];
01199 =       m[0][0] = PC1_1;
01200 =       m[0][1] = PC1_2;
01201 =       m[1][0] = PC2_1;
01202 =       m[1][1] = PC2_2;
01203 *
01204 *     The storage order for this 2-D array is the same as for the 1-D array,
01205 *     whence
01206 *
01207 =       wcs.pc = *m;
01208 *
01209 *     would be legitimate.
01210 *
01211 *   double *cdelt
01212 *     (Given) Address of the first element of an array of double containing
01213 *     the coordinate increments, CDELTia.
01214 *
01215 *   double *crval
01216 *     (Given) Address of the first element of an array of double containing
01217 *     the coordinate reference values, CRVALia.
01218 *
01219 *   char (*cunit)[72]
01220 *     (Given) Address of the first element of an array of char[72] containing
01221 *     the CUNITia keyvalues which define the units of measurement of the
01222 *     CRVALia, CDELTia, and CDi_ja keywords.
01223 *
01224 *     As CUNITia is an optional header keyword, cunit[][72] may be left blank
01225 *     but otherwise is expected to contain a standard units specification as
01226 *     defined by WCS Paper I.  Utility function wcsutrn(), described in
01227 *     wcsunits.h, is available to translate commonly used non-standard units
01228 *     specifications but this must be done as a separate step before invoking
01229 *     wcsset().
01230 *
01231 *     For celestial axes, if cunit[][72] is not blank, wcsset() uses
01232 *     wcsunits() to parse it and scale cdelt[], crval[], and cd[][*] to
01233 *     degrees.  It then resets cunit[][72] to "deg".
01234 *
01235 *     For spectral axes, if cunit[][72] is not blank, wcsset() uses wcsunits()
01236 *     to parse it and scale cdelt[], crval[], and cd[][*] to SI units.  It
01237 *     then resets cunit[][72] accordingly.
01238 *
01239 *     wcsset() ignores cunit[][72] for other coordinate types; cunit[][72] may
01240 *     be used to label coordinate values.
01241 *
01242 *     These variables accomodate the longest allowed string-valued FITS
01243 *     keyword, being limited to 68 characters, plus the null-terminating
01244 *     character.
01245 *
01246 *   char (*ctype)[72]
01247 *     (Given) Address of the first element of an array of char[72] containing
01248 *     the coordinate axis types, CTYPEia.
01249 *
01250 *     The ctype[][72] keyword values must be in upper case and there must be
01251 *     zero or one pair of matched celestial axis types, and zero or one
01252 *     spectral axis.  The ctype[][72] strings should be padded with blanks on
01253 *     the right and null-terminated so that they are at least eight characters
01254 *     in length.
01255 *
01256 *     These variables accomodate the longest allowed string-valued FITS
01257 *     keyword, being limited to 68 characters, plus the null-terminating
01258 *     character.
01259 *
01260 *   double lonpole
01261 *     (Given and returned) The native longitude of the celestial pole, phi_p,
01262 *     given by LONPOLEa [deg] or by PVi_2a [deg] attached to the longitude
01263 *     axis which takes precedence if defined, and ...
01264 *   double latpole
01265 *     (Given and returned) ... the native latitude of the celestial pole,
01266 *     theta_p, given by LATPOLEa [deg] or by PVi_3a [deg] attached to the
01267 *     longitude axis which takes precedence if defined.
01268 *
01269 *     lonpole and latpole may be left to default to values set by wcsinit()
01270 *     (see celprm::ref), but in any case they will be reset by wcsset() to
01271 *     the values actually used.  Note therefore that if the wcsprm struct is
01272 *     reused without resetting them, whether directly or via wcsinit(), they
01273 *     will no longer have their default values.
01274 *
01275 *   double restfrq
01276 *     (Given) The rest frequency [Hz], and/or ...
01277 *   double restwav
```

```
01278 *     (Given) ... the rest wavelength in vacuo [m], only one of which need be
01279 *     given, the other should be set to zero.
01280 *
01281 *   int npv
01282 *     (Given) The number of entries in the wcsprm::pv[] array.
01283 *
01284 *   int npvmax
01285 *     (Given or returned) The length of the wcsprm::pv[] array.
01286 *
01287 *     npvmax will be set by wcsinit() if it allocates memory for wcsprm::pv[],
01288 *     otherwise it must be set by the user.  See also wcsnpv().
01289 *
01290 *   struct pvcard *pv
01291 *     (Given) Address of the first element of an array of length npvmax of
01292 *     pvcard structs.
01293 *
01294 *     As a FITS header parser encounters each PVi_ma keyword it should load it
01295 *     into a pvcard struct in the array and increment npv.  wcsset()
01296 *     interprets these as required.
01297 *
01298 *     Note that, if they were not given, wcsset() resets the entries for
01299 *     PVi_1a, PVi_2a, PVi_3a, and PVi_4a for longitude axis i to match
01300 *     phi_0 and theta_0 (the native longitude and latitude of the reference
01301 *     point), LONPOLEa and LATPOLEa respectively.
01302 *
01303 *   int nps
01304 *     (Given) The number of entries in the wcsprm::ps[] array.
01305 *
01306 *   int npsmax
01307 *     (Given or returned) The length of the wcsprm::ps[] array.
01308 *
01309 *     npsmax will be set by wcsinit() if it allocates memory for wcsprm::ps[],
01310 *     otherwise it must be set by the user.  See also wcsnps().
01311 *
01312 *   struct pscard *ps
01313 *     (Given) Address of the first element of an array of length npsmax of
01314 *     pscard structs.
01315 *
01316 *     As a FITS header parser encounters each PSi_ma keyword it should load it
01317 *     into a pscard struct in the array and increment nps.  wcsset()
01318 *     interprets these as required (currently no PSi_ma keyvalues are
01319 *     recognized).
01320 *
01321 *   double *cd
01322 *     (Given) For historical compatibility, the wcsprm struct supports two
01323 *     alternate specifications of the linear transformation matrix, those
01324 *     associated with the CDi_ja keywords, and ...
01325 *   double *crota
01326 *     (Given) ... those associated with the CROTAi keywords.  Although these
01327 *     may not formally co-exist with PCi_ja, the approach taken here is simply
01328 *     to ignore them if given in conjunction with PCi_ja.
01329 *
01330 *   int altlin
01331 *     (Given) altlin is a bit flag that denotes which of the PCi_ja, CDi_ja
01332 *     and CROTAi keywords are present in the header:
01333 *
01334 *     - Bit 0: PCi_ja is present.
01335 *
01336 *     - Bit 1: CDi_ja is present.
01337 *
01338 *       Matrix elements in the IRAF convention are equivalent to the product
01339 *       CDi_ja = CDELTia * PCi_ja, but the defaults differ from that of the
01340 *       PCi_ja matrix.  If one or more CDi_ja keywords are present then all
01341 *       unspecified CDi_ja default to zero.  If no CDi_ja (or CROTAi) keywords
01342 *       are present, then the header is assumed to be in PCi_ja form whether
01343 *       or not any PCi_ja keywords are present since this results in an
01344 *       interpretation of CDELTia consistent with the original FITS
01345 *       specification.
01346 *
01347 *       While CDi_ja may not formally co-exist with PCi_ja, it may co-exist
01348 *       with CDELTia and CROTAi which are to be ignored.
01349 *
01350 *     - Bit 2: CROTAi is present.
01351 *
01352 *       In the AIPS convention, CROTAi may only be associated with the
01353 *       latitude axis of a celestial axis pair.  It specifies a rotation in
01354 *       the image plane that is applied AFTER the CDELTia; any other CROTAi
01355 *       keywords are ignored.
01356 *
01357 *       CROTAi may not formally co-exist with PCi_ja.
01358 *
01359 *       CROTAi and CDELTia may formally co-exist with CDi_ja but if so are to
01360 *       be ignored.
01361 *
01362 *     - Bit 3: PCi_ja + CDELTia was derived from CDi_ja by wcspcx().
01363 *
01364 *       This bit is set by wcspcx() when it derives PCi_ja and CDELTia from
```

```
01365 *       CDi_ja via an orthonormal decomposition.  In particular, it signals
01366 *       wcsset() not to replace PCi_ja by a copy of CDi_ja with CDELTia set
01367 *       to unity.
01368 *
01369 *     CDi_ja and CROTAi keywords, if found, are to be stored in the wcsprm::cd
01370 *     and wcsprm::crota arrays which are dimensioned similarly to wcsprm::pc
01371 *     and wcsprm::cdelt.  FITS header parsers should use the following
01372 *     procedure:
01373 *
01374 *     - Whenever a PCi_ja keyword is encountered: altlin |= 1;
01375 *
01376 *     - Whenever a CDi_ja keyword is encountered: altlin |= 2;
01377 *
01378 *     - Whenever a CROTAi keyword is encountered: altlin |= 4;
01379 *
01380 *     If none of these bits are set the PCi_ja representation results, i.e.
01381 *     wcsprm::pc and wcsprm::cdelt will be used as given.
01382 *
01383 *     These alternate specifications of the linear transformation matrix are
01384 *     translated immediately to PCi_ja by wcsset() and are invisible to the
01385 *     lower-level WCSLIB routines.  In particular, unless bit 3 is also set,
01386 *     wcsset() resets wcsprm::cdelt to unity if CDi_ja is present (and no
01387 *     PCi_ja).
01388 *
01389 *     If CROTAi are present but none is associated with the latitude axis
01390 *     (and no PCi_ja or CDi_ja), then wcsset() reverts to a unity PCi_ja
01391 *     matrix.
01392 *
01393 *   int velref
01394 *     (Given) AIPS velocity code VELREF, refer to spcaips().
01395 *
01396 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01397 *     wcsprm::velref is changed.
01398 *
01399 *   char alt[4]
01400 *     (Given, auxiliary) Character code for alternate coordinate descriptions
01401 *     (i.e. the 'a' in keyword names such as CTYPEia).  This is blank for the
01402 *     primary coordinate description, or one of the 26 upper-case letters,
01403 *     A-Z.
01404 *
01405 *     An array of four characters is provided for alignment purposes, only the
01406 *     first is used.
01407 *
01408 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01409 *     wcsprm::alt is changed.
01410 *
01411 *   int colnum
01412 *     (Given, auxiliary) Where the coordinate representation is associated
01413 *     with an image-array column in a FITS binary table, this variable may be
01414 *     used to record the relevant column number.
01415 *
01416 *     It should be set to zero for an image header or pixel list.
01417 *
01418 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01419 *     wcsprm::colnum is changed.
01420 *
01421 *   int *colax
01422 *     (Given, auxiliary) Address of the first element of an array of int
01423 *     recording the column numbers for each axis in a pixel list.
01424 *
01425 *     The array elements should be set to zero for an image header or image
01426 *     array in a binary table.
01427 *
01428 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01429 *     wcsprm::colax is changed.
01430 *
01431 *   char (*cname)[72]
01432 *     (Given, auxiliary) The address of the first element of an array of
01433 *     char[72] containing the coordinate axis names, CNAMEia.
01434 *
01435 *     These variables accomodate the longest allowed string-valued FITS
01436 *     keyword, being limited to 68 characters, plus the null-terminating
01437 *     character.
01438 *
01439 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01440 *     wcsprm::cname is changed.
01441 *
01442 *   double *crder
01443 *     (Given, auxiliary) Address of the first element of an array of double
01444 *     recording the random error in the coordinate value, CRDERia.
01445 *
01446 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01447 *     wcsprm::crder is changed.
01448 *
01449 *   double *csyer
01450 *     (Given, auxiliary) Address of the first element of an array of double
01451 *     recording the systematic error in the coordinate value, CSYERia.
```

```
01452 *
01453 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01454 *     wcsprm::csyer is changed.
01455 *
01456 *   double *czphs
01457 *     (Given, auxiliary) Address of the first element of an array of double
01458 *     recording the time at the zero point of a phase axis, CZPHSia.
01459 *
01460 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01461 *     wcsprm::czphs is changed.
01462 *
01463 *   double *cperi
01464 *     (Given, auxiliary) Address of the first element of an array of double
01465 *     recording the period of a phase axis, CPERIia.
01466 *
01467 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01468 *     wcsprm::cperi is changed.
01469 *
01470 *   char wcsname[72]
01471 *     (Given, auxiliary) The name given to the coordinate representation,
01472 *     WCSNAMEa.  This variable accomodates the longest allowed string-valued
01473 *     FITS keyword, being limited to 68 characters, plus the null-terminating
01474 *     character.
01475 *
01476 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01477 *     wcsprm::wcsname is changed.
01478 *
01479 *   char timesys[72]
01480 *     (Given, auxiliary) TIMESYS keyvalue, being the time scale (UTC, TAI,
01481 *     etc.) in which all other time-related auxiliary header values are
01482 *     recorded.  Also defines the time scale for an image axis with CTYPEia
01483 *     set to 'TIME'.
01484 *
01485 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01486 *     wcsprm::timesys is changed.
01487 *
01488 *   char trefpos[72]
01489 *     (Given, auxiliary) TREFPOS keyvalue, being the location in space where
01490 *     the recorded time is valid.
01491 *
01492 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01493 *     wcsprm::trefpos is changed.
01494 *
01495 *   char trefdir[72]
01496 *     (Given, auxiliary) TREFDIR keyvalue, being the reference direction used
01497 *     in calculating a pathlength delay.
01498 *
01499 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01500 *     wcsprm::trefdir is changed.
01501 *
01502 *   char plephem[72]
01503 *     (Given, auxiliary) PLEPHEM keyvalue, being the Solar System ephemeris
01504 *     used for calculating a pathlength delay.
01505 *
01506 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01507 *     wcsprm::plephem is changed.
01508 *
01509 *   char timeunit[72]
01510 *     (Given, auxiliary) TIMEUNIT keyvalue, being the time units in which
01511 *     the following header values are expressed: TSTART, TSTOP, TIMEOFFS,
01512 *     TIMSYER, TIMRDER, TIMEDEL.  It also provides the default value for
01513 *     CUNITia for time axes.
01514 *
01515 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01516 *     wcsprm::timeunit is changed.
01517 *
01518 *   char dateref[72]
01519 *     (Given, auxiliary) DATEREF keyvalue, being the date of a reference epoch
01520 *     relative to which other time measurements refer.
01521 *
01522 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01523 *     wcsprm::dateref is changed.
01524 *
01525 *   double mjdref[2]
01526 *     (Given, auxiliary) MJDREF keyvalue, equivalent to DATEREF expressed as
01527 *     a Modified Julian Date (MJD = JD - 2400000.5).  The value is given as
01528 *     the sum of the two-element vector, allowing increased precision.
01529 *
01530 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01531 *     wcsprm::mjdref is changed.
01532 *
01533 *   double timeoffs
01534 *     (Given, auxiliary) TIMEOFFS keyvalue, being a time offset, which may be
01535 *     used, for example, to provide a uniform clock correction for times
01536 *     referenced to DATEREF.
01537 *
01538 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
```

```
01539 *     wcsprm::timeoffs is changed.
01540 *
01541 *   char dateobs[72]
01542 *     (Given, auxiliary) DATE-OBS keyvalue, being the date at the start of the
01543 *     observation unless otherwise explained in the DATE-OBS keycomment, in
01544 *     ISO format, yyyy-mm-ddThh:mm:ss.
01545 *
01546 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01547 *     wcsprm::dateobs is changed.
01548 *
01549 *   char datebeg[72]
01550 *     (Given, auxiliary) DATE-BEG keyvalue, being the date at the start of the
01551 *     observation in ISO format, yyyy-mm-ddThh:mm:ss.
01552 *
01553 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01554 *     wcsprm::datebeg is changed.
01555 *
01556 *   char dateavg[72]
01557 *     (Given, auxiliary) DATE-AVG keyvalue, being the date at a representative
01558 *     mid-point of the observation in ISO format, yyyy-mm-ddThh:mm:ss.
01559 *
01560 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01561 *     wcsprm::dateavg is changed.
01562 *
01563 *   char dateend[72]
01564 *     (Given, auxiliary) DATE-END keyvalue, baing the date at the end of the
01565 *     observation in ISO format, yyyy-mm-ddThh:mm:ss.
01566 *
01567 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01568 *     wcsprm::dateend is changed.
01569 *
01570 *   double mjdobs
01571 *     (Given, auxiliary) MJD-OBS keyvalue, equivalent to DATE-OBS expressed
01572 *     as a Modified Julian Date (MJD = JD - 2400000.5).
01573 *
01574 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01575 *     wcsprm::mjdobs is changed.
01576 *
01577 *   double mjdbeg
01578 *     (Given, auxiliary) MJD-BEG keyvalue, equivalent to DATE-BEG expressed
01579 *     as a Modified Julian Date (MJD = JD - 2400000.5).
01580 *
01581 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01582 *     wcsprm::mjdbeg is changed.
01583 *
01584 *   double mjdavg
01585 *     (Given, auxiliary) MJD-AVG keyvalue, equivalent to DATE-AVG expressed
01586 *     as a Modified Julian Date (MJD = JD - 2400000.5).
01587 *
01588 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01589 *     wcsprm::mjdavg is changed.
01590 *
01591 *   double mjdend
01592 *     (Given, auxiliary) MJD-END keyvalue, equivalent to DATE-END expressed
01593 *     as a Modified Julian Date (MJD = JD - 2400000.5).
01594 *
01595 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01596 *     wcsprm::mjdend is changed.
01597 *
01598 *   double jepoch
01599 *     (Given, auxiliary) JEPOCH keyvalue, equivalent to DATE-OBS expressed
01600 *     as a Julian epoch.
01601 *
01602 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01603 *     wcsprm::jepoch is changed.
01604 *
01605 *   double bepoch
01606 *     (Given, auxiliary) BEPOCH keyvalue, equivalent to DATE-OBS expressed
01607 *     as a Besselian epoch
01608 *
01609 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01610 *     wcsprm::bepoch is changed.
01611 *
01612 *   double tstart
01613 *     (Given, auxiliary) TSTART keyvalue, equivalent to DATE-BEG expressed
01614 *     as a time in units of TIMEUNIT relative to DATEREF+TIMEOFFS.
01615 *
01616 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01617 *     wcsprm::tstart is changed.
01618 *
01619 *   double tstop
01620 *     (Given, auxiliary) TSTOP keyvalue, equivalent to DATE-END expressed
01621 *     as a time in units of TIMEUNIT relative to DATEREF+TIMEOFFS.
01622 *
01623 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01624 *     wcsprm::tstop is changed.
01625 *
```

```
01626 *   double xposure
01627 *     (Given, auxiliary) XPOSURE keyvalue, being the effective exposure time
01628 *     in units of TIMEUNIT.
01629 *
01630 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01631 *     wcsprm::xposure is changed.
01632 *
01633 *   double telapse
01634 *     (Given, auxiliary) TELAPSE keyvalue, equivalent to the elapsed time
01635 *     between DATE-BEG and DATE-END, in units of TIMEUNIT.
01636 *
01637 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01638 *     wcsprm::telapse is changed.
01639 *
01640 *   double timsyer
01641 *     (Given, auxiliary) TIMSYER keyvalue, being the absolute error of the
01642 *     time values, in units of TIMEUNIT.
01643 *
01644 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01645 *     wcsprm::timsyer is changed.
01646 *
01647 *   double timrder
01648 *     (Given, auxiliary) TIMRDER keyvalue, being the accuracy of time stamps
01649 *     relative to each other, in units of TIMEUNIT.
01650 *
01651 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01652 *     wcsprm::timrder is changed.
01653 *
01654 *   double timedel
01655 *     (Given, auxiliary) TIMEDEL keyvalue, being the resolution of the time
01656 *     stamps.
01657 *
01658 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01659 *     wcsprm::timedel is changed.
01660 *
01661 *   double timepixr
01662 *     (Given, auxiliary) TIMEPIXR keyvalue, being the relative position of the
01663 *     time stamps in binned time intervals, a value between 0.0 and 1.0.
01664 *
01665 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01666 *     wcsprm::timepixr is changed.
01667 *
01668 *   double obsgeo[6]
01669 *     (Given, auxiliary) Location of the observer in a standard terrestrial
01670 *     reference frame.  The first three give ITRS Cartesian coordinates
01671 *     OBSGEO-X [m],   OBSGEO-Y [m],   OBSGEO-Z [m], and the second three give
01672 *     OBSGEO-L [deg], OBSGEO-B [deg], OBSGEO-H [m], which are related through
01673 *     a standard transformation.
01674 *
01675 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01676 *     wcsprm::obsgeo is changed.
01677 *
01678 *   char obsorbit[72]
01679 *     (Given, auxiliary) OBSORBIT keyvalue, being the URI, URL, or name of an
01680 *     orbit ephemeris file giving spacecraft coordinates relating to TREFPOS.
01681 *
01682 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01683 *     wcsprm::obsorbit is changed.
01684 *
01685 *   char radesys[72]
01686 *     (Given, auxiliary) The equatorial or ecliptic coordinate system type,
01687 *     RADESYSa.
01688 *
01689 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01690 *     wcsprm::radesys is changed.
01691 *
01692 *   double equinox
01693 *     (Given, auxiliary) The equinox associated with dynamical equatorial or
01694 *     ecliptic coordinate systems, EQUINOXa (or EPOCH in older headers).  Not
01695 *     applicable to ICRS equatorial or ecliptic coordinates.
01696 *
01697 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01698 *     wcsprm::equinox is changed.
01699 *
01700 *   char specsys[72]
01701 *     (Given, auxiliary) Spectral reference frame (standard of rest),
01702 *     SPECSYSa.
01703 *
01704 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01705 *     wcsprm::specsys is changed.
01706 *
01707 *   char ssysobs[72]
01708 *     (Given, auxiliary) The spectral reference frame in which there is no
01709 *     differential variation in the spectral coordinate across the
01710 *     field-of-view, SSYSOBSa.
01711 *
01712 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
```

```
01713 *     wcsprm::ssysobs is changed.
01714 *
01715 *   double velosys
01716 *     (Given, auxiliary) The relative radial velocity [m/s] between the
01717 *     observer and the selected standard of rest in the direction of the
01718 *     celestial reference coordinate, VELOSYSa.
01719 *
01720 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01721 *     wcsprm::velosys is changed.
01722 *
01723 *   double zsource
01724 *     (Given, auxiliary) The redshift, ZSOURCEa, of the source.
01725 *
01726 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01727 *     wcsprm::zsource is changed.
01728 *
01729 *   char ssyssrc[72]
01730 *     (Given, auxiliary) The spectral reference frame (standard of rest),
01731 *     SSYSSRCa, in which wcsprm::zsource was measured.
01732 *
01733 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01734 *     wcsprm::ssyssrc is changed.
01735 *
01736 *   double velangl
01737 *     (Given, auxiliary) The angle [deg] that should be used to decompose an
01738 *     observed velocity into radial and transverse components.
01739 *
01740 *     It is not necessary to reset the wcsprm struct (via wcsset()) when
01741 *     wcsprm::velangl is changed.
01742 *
01743 *   struct auxprm *aux
01744 *     (Given, auxiliary) This struct holds auxiliary coordinate system
01745 *     information of a specialist nature.  While these parameters may be
01746 *     widely recognized within particular fields of astronomy, they differ
01747 *     from the above auxiliary parameters in not being defined by any of the
01748 *     FITS WCS standards.  Collecting them together in a separate struct that
01749 *     is allocated only when required helps to control bloat in the size of
01750 *     the wcsprm struct.
01751 *
01752 *   int ntab
01753 *     (Given) See wcsprm::tab.
01754 *
01755 *   int nwtb
01756 *     (Given) See wcsprm::wtb.
01757 *
01758 *   struct tabprm *tab
01759 *     (Given) Address of the first element of an array of ntab tabprm structs
01760 *     for which memory has been allocated.  These are used to store tabular
01761 *     transformation parameters.
01762 *
01763 *     Although technically wcsprm::ntab and tab are "given", they will
01764 *     normally be set by invoking wcstab(), whether directly or indirectly.
01765 *
01766 *     The tabprm structs contain some members that must be supplied and others
01767 *     that are derived.  The information to be supplied comes primarily from
01768 *     arrays stored in one or more FITS binary table extensions.  These
01769 *     arrays, referred to here as "wcstab arrays", are themselves located by
01770 *     parameters stored in the FITS image header.
01771 *
01772 *   struct wtbarr *wtb
01773 *     (Given) Address of the first element of an array of nwtb wtbarr structs
01774 *     for which memory has been allocated.  These are used in extracting
01775 *     wcstab arrays from a FITS binary table.
01776 *
01777 *     Although technically wcsprm::nwtb and wtb are "given", they will
01778 *     normally be set by invoking wcstab(), whether directly or indirectly.
01779 *
01780 *   char lngtyp[8]
01781 *     (Returned) Four-character WCS celestial longitude and ...
01782 *   char lattyp[8]
01783 *     (Returned) ... latitude axis types. e.g. "RA", "DEC", "GLON", "GLAT",
01784 *     etc. extracted from 'RA--', 'DEC-', 'GLON', 'GLAT', etc. in the first
01785 *     four characters of CTYPEia but with trailing dashes removed.  (Declared
01786 *     as char[8] for alignment reasons.)
01787 *
01788 *   int lng
01789 *     (Returned) Index for the longitude coordinate, and ...
01790 *   int lat
01791 *     (Returned) ... index for the latitude coordinate, and ...
01792 *   int spec
01793 *     (Returned) ... index for the spectral coordinate, and ...
01794 *   int time
01795 *     (Returned) ... index for the time coordinate in the imgcrd[][] and
01796 *     world[][] arrays in the API of wcsp2s(), wcss2p() and wcsmix().
01797 *
01798 *     These may also serve as indices into the pixcrd[][] array provided that
01799 *     the PCi_ja matrix does not transpose axes.
```

```
01800 *
01801 *   int cubeface
01802 *     (Returned) Index into the pixcrd[][] array for the CUBEFACE axis.  This
01803 *     is used for quadcube projections where the cube faces are stored on a
01804 *     separate axis (see wcs.h).
01805 *
01806 *   int *types
01807 *     (Returned) Address of the first element of an array of int containing a
01808 *     four-digit type code for each axis.
01809 *
01810 *     - First digit (i.e. 1000s):
01811 *       - 0: Non-specific coordinate type.
01812 *       - 1: Stokes coordinate.
01813 *       - 2: Celestial coordinate (including CUBEFACE).
01814 *       - 3: Spectral coordinate.
01815 *       - 4: Time coordinate.
01816 *
01817 *     - Second digit (i.e. 100s):
01818 *       - 0: Linear axis.
01819 *       - 1: Quantized axis (STOKES, CUBEFACE).
01820 *       - 2: Non-linear celestial axis.
01821 *       - 3: Non-linear spectral axis.
01822 *       - 4: Logarithmic axis.
01823 *       - 5: Tabular axis.
01824 *
01825 *     - Third digit (i.e. 10s):
01826 *       - 0: Group number, e.g. lookup table number, being an index into the
01827 *            tabprm array (see above).
01828 *
01829 *     - The fourth digit is used as a qualifier depending on the axis type.
01830 *
01831 *       - For celestial axes:
01832 *         - 0: Longitude coordinate.
01833 *         - 1: Latitude coordinate.
01834 *         - 2: CUBEFACE number.
01835 *
01836 *       - For lookup tables: the axis number in a multidimensional table.
01837 *
01838 *     CTYPEia in "4-3" form with unrecognized algorithm code will have its
01839 *     type set to -1 and generate an error.
01840 *
01841 *   struct linprm lin
01842 *     (Returned) Linear transformation parameters (usage is described in the
01843 *     prologue to lin.h).
01844 *
01845 *   struct celprm cel
01846 *     (Returned) Celestial transformation parameters (usage is described in
01847 *     the prologue to cel.h).
01848 *
01849 *   struct spcprm spc
01850 *     (Returned) Spectral transformation parameters (usage is described in the
01851 *     prologue to spc.h).
01852 *
01853 *   struct wcserr *err
01854 *     (Returned) If enabled, when an error status is returned, this struct
01855 *     contains detailed information about the error, see wcserr_enable().
01856 *
01857 *   int m_flag
01858 *     (For internal use only.)
01859 *   int m_naxis
01860 *     (For internal use only.)
01861 *   double *m_crpix
01862 *     (For internal use only.)
01863 *   double *m_pc
01864 *     (For internal use only.)
01865 *   double *m_cdelt
01866 *     (For internal use only.)
01867 *   double *m_crval
01868 *     (For internal use only.)
01869 *   char (*m_cunit)[72]
01870 *     (For internal use only.)
01871 *   char (*m_ctype)[72]
01872 *     (For internal use only.)
01873 *   struct pvcard *m_pv
01874 *     (For internal use only.)
01875 *   struct pscard *m_ps
01876 *     (For internal use only.)
01877 *   double *m_cd
01878 *     (For internal use only.)
01879 *   double *m_crota
01880 *     (For internal use only.)
01881 *   int *m_colax
01882 *     (For internal use only.)
01883 *   char (*m_cname)[72]
01884 *     (For internal use only.)
01885 *   double *m_crder
01886 *     (For internal use only.)
```

```
01887 *   double *m_csyer
01888 *     (For internal use only.)
01889 *   double *m_czphs
01890 *     (For internal use only.)
01891 *   double *m_cperi
01892 *     (For internal use only.)
01893 *   struct tabprm *m_tab
01894 *     (For internal use only.)
01895 *   struct wtbarr *m_wtb
01896 *     (For internal use only.)
01897 *
01898 *
01899 * pvcard struct - Store for PVi_ma keyrecords
01900 * ------------------------------------------
01901 * The pvcard struct is used to pass the parsed contents of PVi_ma keyrecords
01902 * to wcsset() via the wcsprm struct.
01903 *
01904 * All members of this struct are to be set by the user.
01905 *
01906 *   int i
01907 *     (Given) Axis number (1-relative), as in the FITS PVi_ma keyword.  If
01908 *     i == 0, wcsset() will replace it with the latitude axis number.
01909 *
01910 *   int m
01911 *     (Given) Parameter number (non-negative), as in the FITS PVi_ma keyword.
01912 *
01913 *   double value
01914 *     (Given) Parameter value.
01915 *
01916 *
01917 * pscard struct - Store for PSi_ma keyrecords
01918 * ------------------------------------------
01919 * The pscard struct is used to pass the parsed contents of PSi_ma keyrecords
01920 * to wcsset() via the wcsprm struct.
01921 *
01922 * All members of this struct are to be set by the user.
01923 *
01924 *   int i
01925 *     (Given) Axis number (1-relative), as in the FITS PSi_ma keyword.
01926 *
01927 *   int m
01928 *     (Given) Parameter number (non-negative), as in the FITS PSi_ma keyword.
01929 *
01930 *   char value[72]
01931 *     (Given) Parameter value.
01932 *
01933 *
01934 * auxprm struct - Additional auxiliary parameters
01935 * ----------------------------------------------
01936 * The auxprm struct holds auxiliary coordinate system information of a
01937 * specialist nature.  It is anticipated that this struct will expand in future
01938 * to accomodate additional parameters.
01939 *
01940 * All members of this struct are to be set by the user.
01941 *
01942 *   double rsun_ref
01943 *     (Given, auxiliary) Reference radius of the Sun used in coordinate
01944 *     calculations (m).
01945 *
01946 *   double dsun_obs
01947 *     (Given, auxiliary) Distance between the centre of the Sun and the
01948 *     observer (m).
01949 *
01950 *   double crln_obs
01951 *     (Given, auxiliary) Carrington heliographic longitude of the observer
01952 *     (deg).
01953 *
01954 *   double hgln_obs
01955 *     (Given, auxiliary) Stonyhurst heliographic longitude of the observer
01956 *     (deg).
01957 *
01958 *   double hglt_obs
01959 *     (Given, auxiliary) Heliographic latitude (Carrington or Stonyhurst) of
01960 *     the observer (deg).
01961 *
01962 *   double a_radius
01963 *     Length of the semi-major axis of a triaxial ellipsoid approximating the
01964 *     shape of a body (e.g. planet) in the solar system (m).
01965 *
01966 *   double b_radius
01967 *     Length of the intermediate axis, normal to the semi-major and semi-minor
01968 *     axes, of a triaxial ellipsoid approximating the shape of a body (m).
01969 *
01970 *   double c_radius
01971 *     Length of the semi-minor axis, normal to the semi-major axis, of a
01972 *     triaxial ellipsoid approximating the shape of a body (m).
01973 *
```

```
01974 *   double blon_obs
01975 *     Bodycentric longitude of the observer in the coordinate system fixed to
01976 *     the planet or other solar system body (deg, in range 0 to 360).
01977 *
01978 *   double blat_obs
01979 *     Bodycentric latitude of the observer in the coordinate system fixed to
01980 *     the planet or other solar system body (deg).
01981 *
01982 *   double bdis_obs
01983 *     Bodycentric distance of the observer (m).
01984 *
01985 * Global variable: const char *wcs_errmsg[] - Status return messages
01986 * ------------------------------------------------------------------
01987 * Error messages to match the status value returned from each function.
01988 *
01989 *===========================================================================*/

6.25 wcserr.h File Reference

Data Structures

- struct wcserr

  Error message handling.

Macros

- #define ERRLEN (sizeof(struct wcserr)/sizeof(int))
- #define WCSERR_SET(status) err, status, function, __FILE__, __LINE__

  Fill in the contents of an error object.

Functions

- int wcserr_enable (int enable)

  Enable/disable error messaging.
- int wcserr_size (const struct wcserr *err, int sizes[2])

  Compute the size of a wcserr struct.
- int wcserr_prt (const struct wcserr *err, const char *prefix)

  Print a wcserr struct.
- int wcserr_clear (struct wcserr **err)

  Clear a wcserr struct.
- int wcserr_set (struct wcserr **err, int status, const char *function, const char *file, int line_no, const char *format,...)

  Fill in the contents of an error object.
- int wcserr_copy (const struct wcserr *src, struct wcserr *dst)

  Copy an error object.

6.25.1 Detailed Description

Most of the structs in WCSLIB contain a pointer to a wcserr struct as a member. Functions in WCSLIB that return an error status code can also allocate and set a detailed error message in this struct, which also identifies the function, source file, and line number where the error occurred.

For example:

```
struct prjprm prj;
wcserr_enable(1);
if (prjini(&prj)) {
  // Print the error message to stderr.
  wcsprintf_set(stderr);
  wcserr_prt(prj.err, 0x0);
}
```

A number of utility functions used in managing the wcserr struct are for **internal use only**. They are documented here solely as an aid to understanding the code. They are not intended for external use - the API may change without notice!

6.25.2 Macro Definition Documentation

ERRLEN

```
#define ERRLEN (sizeof(struct wcserr)/sizeof(int))
```

WCSERR_SET

```
#define WCSERR_SET(
              status ) err, status, function, __FILE__, __LINE__
```

Fill in the contents of an error object.

INTERNAL USE ONLY.

WCSERR_SET() is a preprocessor macro that helps to fill in the argument list of wcserr_set(). It takes status as an argument of its own and provides the name of the source file and the line number at the point where invoked. It assumes that the err and function arguments of wcserr_set() will be provided by variables of the same names.

6.25.3 Function Documentation

wcserr_enable()

```
int wcserr_enable (
            int enable )
```

Enable/disable error messaging.

wcserr_enable() enables or disables wcserr error messaging. By default it is disabled.

PLEASE NOTE: This function is not thread-safe.

Parameters

in	*enable*	If true (non-zero), enable error messaging, else disable it.

Returns

Status return value:

- 0: Error messaging is disabled.
- 1: Error messaging is enabled.

wcserr_size()

```
int wcserr_size (
            const struct wcserr * err,
            int sizes[2] )
```

Compute the size of a wcserr struct.

wcserr_size() computes the full size of a wcserr struct, including allocated memory.

Parameters

in	*err*	The error object. If NULL, the base size of the struct and the allocated size are both set to zero.
out	*sizes*	The first element is the base size of the struct as returned by sizeof(struct wcserr). The second element is the total allocated size of the message buffer, in bytes.

Returns

Status return value:

- 0: Success.

wcserr_prt()

```
int wcserr_prt (
            const struct wcserr * err,
            const char * prefix )
```

Print a wcserr struct.

wcserr_prt() prints the error message (if any) contained in a wcserr struct. It uses the wcsprintf() functions.

Parameters

in	*err*	The error object. If NULL, nothing is printed.
in	*prefix*	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 2: Error messaging is not enabled.

wcserr_clear()

```
int wcserr_clear (
             struct wcserr ** err )
```

Clear a wcserr struct.

wcserr_clear() clears (deletes) a wcserr struct.

Parameters

in,out	*err*	The error object. If NULL, nothing is done. Set to NULL on return.

Returns

Status return value:

- 0: Success.

wcserr_set()

```
int wcserr_set (
             struct wcserr ** err,
             int status,
             const char * function,
             const char * file,
             int line_no,
             const char * format,
              ... )
```

Fill in the contents of an error object.

INTERNAL USE ONLY.

wcserr_set() fills a wcserr struct with information about an error.

A convenience macro, WCSERR_SET, provides the source file and line number information automatically.

Parameters

in,out	*err*	Error object. If err is NULL, returns the status code given without setting an error message. If ∗err is NULL, allocates memory for a wcserr struct (provided that status is non-zero).
in	*status*	Numeric status code to set. If 0, then ∗err will be deleted and ∗err will be returned as NULL.
in	*function*	Name of the function generating the error. This must point to a constant string, i.e. in the initialized read-only data section ("data") of the executable.
in	*file*	Name of the source file generating the error. This must point to a constant string, i.e. in the initialized read-only data section ("data") of the executable such as given by the __FILE__ preprocessor macro.
in	*line_no*	Line number in the source file generating the error such as given by the __LINE__ preprocessor macro.
in	*format*	Format string of the error message. May contain printf-style %-formatting codes.
in	...	The remaining variable arguments are applied (like printf) to the format string to generate the error message.

Returns

The status return code passed in.

wcserr_copy()

```
int wcserr_copy (
             const struct wcserr * src,
             struct wcserr * dst )
```

Copy an error object.

INTERNAL USE ONLY.

wcserr_copy() copies one error object to another. Use of this function should be avoided in general since the function, source file, and line number information copied to the destination may lose its context.

Parameters

in	*src*	Source error object. If src is NULL, dst is cleared.
out	*dst*	Destination error object. If NULL, no copy is made.

Returns

Numeric status code of the source error object.

00024 *=============================================================================
00025 *
00026 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00027 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00028 * overview of the library.
00029 *
00030 * Summary of the wcserr routines
00031 * ------------------------------
00032 * Most of the structs in WCSLIB contain a pointer to a wcserr struct as a
00033 * member.  Functions in WCSLIB that return an error status code can also
00034 * allocate and set a detailed error message in this struct, which also
00035 * identifies the function, source file, and line number where the error
00036 * occurred.
00037 *
00038 * For example:
00039 *
00040 =     struct prjprm prj;
00041 =     wcserr_enable(1);
00042 =     if (prjini(&prj)) {
00043 =       // Print the error message to stderr.
00044 =       wcsprintf_set(stderr);
00045 =       wcserr_prt(prj.err, 0x0);
00046 =     }
00047 *
00048 * A number of utility functions used in managing the wcserr struct are for
00049 * internal use only.  They are documented here solely as an aid to
00050 * understanding the code.  They are not intended for external use - the API
00051 * may change without notice!
00052 *
00053 *
00054 * wcserr struct - Error message handling
00055 * --------------------------------------
00056 * The wcserr struct contains the numeric error code, a textual description of
00057 * the error, and information about the function, source file, and line number
00058 * where the error was generated.
00059 *
00060 *   int status
00061 *     Numeric status code associated with the error, the meaning of which
00062 *     depends on the function that generated it.  See the documentation for
00063 *     the particular function.
00064 *
00065 *   int line_no
00066 *     Line number where the error occurred as given by the __LINE__
00067 *     preprocessor macro.
00068 *
00069 *   const char *function
00070 *     Name of the function where the error occurred.
00071 *
00072 *   const char *file
00073 *     Name of the source file where the error occurred as given by the
00074 *     __FILE__ preprocessor macro.
00075 *
00076 *   char *msg
00077 *     Informative error message.
00078 *
00079 *
00080 * wcserr_enable() - Enable/disable error messaging
00081 * ------------------------------------------------
00082 * wcserr_enable() enables or disables wcserr error messaging.  By default it
00083 * is disabled.
00084 *
00085 * PLEASE NOTE: This function is not thread-safe.
00086 *
00087 * Given:
00088 *   enable    int       If true (non-zero), enable error messaging, else
00089 *                       disable it.
00090 *
00091 * Function return value:
```

```
00092 *             int       Status return value:
00093 *                         0: Error messaging is disabled.
00094 *                         1: Error messaging is enabled.
00095 *
00096 *
00097 * wcserr_size() - Compute the size of a wcserr struct
00098 * --------------------------------------------------
00099 * wcserr_size() computes the full size of a wcserr struct, including allocated
00100 * memory.
00101 *
00102 * Given:
00103 *   err       const struct wcserr*
00104 *                       The error object.
00105 *
00106 *                       If NULL, the base size of the struct and the allocated
00107 *                       size are both set to zero.
00108 *
00109 * Returned:
00110 *   sizes     int[2]    The first element is the base size of the struct as
00111 *                       returned by sizeof(struct wcserr).  The second element
00112 *                       is the total allocated size of the message buffer, in
00113 *                       bytes.
00114 *
00115 * Function return value:
00116 *             int       Status return value:
00117 *                         0: Success.
00118 *
00119 *
00120 * wcserr_prt() - Print a wcserr struct
00121 * ------------------------------------
00122 * wcserr_prt() prints the error message (if any) contained in a wcserr struct.
00123 * It uses the wcsprintf() functions.
00124 *
00125 * Given:
00126 *   err       const struct wcserr*
00127 *                       The error object.  If NULL, nothing is printed.
00128 *
00129 *   prefix    const char *
00130 *                       If non-NULL, each output line will be prefixed with
00131 *                       this string.
00132 *
00133 * Function return value:
00134 *             int       Status return value:
00135 *                         0: Success.
00136 *                         2: Error messaging is not enabled.
00137 *
00138 *
00139 * wcserr_clear() - Clear a wcserr struct
00140 * --------------------------------------
00141 * wcserr_clear() clears (deletes) a wcserr struct.
00142 *
00143 * Given and returned:
00144 *   err       struct wcserr**
00145 *                       The error object.  If NULL, nothing is done.  Set to
00146 *                       NULL on return.
00147 *
00148 * Function return value:
00149 *             int       Status return value:
00150 *                         0: Success.
00151 *
00152 *
00153 * wcserr_set() - Fill in the contents of an error object
00154 * ------------------------------------------------------
00155 * INTERNAL USE ONLY.
00156 *
00157 * wcserr_set() fills a wcserr struct with information about an error.
00158 *
00159 * A convenience macro, WCSERR_SET, provides the source file and line number
00160 * information automatically.
00161 *
00162 * Given and returned:
00163 *   err       struct wcserr**
00164 *                       Error object.
00165 *
00166 *                       If err is NULL, returns the status code given without
00167 *                       setting an error message.
00168 *
00169 *                       If *err is NULL, allocates memory for a wcserr struct
00170 *                       (provided that status is non-zero).
00171 *
00172 * Given:
00173 *   status    int       Numeric status code to set.  If 0, then *err will be
00174 *                       deleted and *err will be returned as NULL.
00175 *
00176 *   function  const char *
00177 *                       Name of the function generating the error.  This
00178 *                       must point to a constant string, i.e. in the
```

```
00179 *                       initialized read-only data section ("data") of the
00180 *                       executable.
00181 *
00182 *   file      const char *
00183 *                       Name of the source file generating the error.  This
00184 *                       must point to a constant string, i.e. in the
00185 *                       initialized read-only data section ("data") of the
00186 *                       executable such as given by the __FILE__ preprocessor
00187 *                       macro.
00188 *
00189 *   line_no   int       Line number in the source file generating the error
00190 *                       such as given by the __LINE__ preprocessor macro.
00191 *
00192 *   format    const char *
00193 *                       Format string of the error message.  May contain
00194 *                       printf-style %-formatting codes.
00195 *
00196 *   ...       mixed     The remaining variable arguments are applied (like
00197 *                       printf) to the format string to generate the error
00198 *                       message.
00199 *
00200 * Function return value:
00201 *             int       The status return code passed in.
00202 *
00203 *
00204 * wcserr_copy() - Copy an error object
00205 * ------------------------------------
00206 * INTERNAL USE ONLY.
00207 *
00208 * wcserr_copy() copies one error object to another.  Use of this function
00209 * should be avoided in general since the function, source file, and line
00210 * number information copied to the destination may lose its context.
00211 *
00212 * Given:
00213 *   src       const struct wcserr*
00214 *                       Source error object.  If src is NULL, dst is cleared.
00215 *
00216 * Returned:
00217 *   dst       struct wcserr*
00218 *                       Destination error object.  If NULL, no copy is made.
00219 *
00220 * Function return value:
00221 *             int       Numeric status code of the source error object.
00222 *
00223 *
00224 * WCSERR_SET() macro - Fill in the contents of an error object
00225 * ------------------------------------------------------------
00226 * INTERNAL USE ONLY.
00227 *
00228 * WCSERR_SET() is a preprocessor macro that helps to fill in the argument list
00229 * of wcserr_set().  It takes status as an argument of its own and provides the
00230 * name of the source file and the line number at the point where invoked.  It
00231 * assumes that the err and function arguments of wcserr_set() will be provided
00232 * by variables of the same names.
00233 *

Functions

- int wcsfix (int ctrl, const int naxis[ ], struct wcsprm *wcs, int stat[ ])

  Translate a non-standard WCS struct.
- int wcsfixi (int ctrl, const int naxis[ ], struct wcsprm *wcs, int stat[ ], struct wcserr info[ ])

  Translate a non-standard WCS struct.
- int cdfix (struct wcsprm *wcs)

  *Fix erroneously omitted **CD**i_ja keywords.*
- int datfix (struct wcsprm *wcs)

  *Translate **DATE-OBS** and derive **MJD-OBS** or vice versa.*
- int obsfix (int ctrl, struct wcsprm *wcs)

  *complete the **OBS**GEO-[XYZLBH] vector of observatory coordinates.*
- int unitfix (int ctrl, struct wcsprm *wcs)

  *Correct aberrant **CUNIT**ia keyvalues.*
- int spcfix (struct wcsprm *wcs)

  Translate AIPS-convention spectral types.
- int celfix (struct wcsprm *wcs)

  Translate AIPS-convention celestial projection types.
- int cylfix (const int naxis[ ], struct wcsprm *wcs)

  Fix malformed cylindrical projections.
- int wcspcx (struct wcsprm *wcs, int dopc, int permute, double rotn[2])

  regularize PCi_j.

Variables

- const char * wcsfix_errmsg [ ]

  Status return messages.

6.27.1 Detailed Description

Routines in this suite identify and translate various forms of construct known to occur in FITS headers that violate the FITS World Coordinate System (WCS) standard described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)

"Representations of time coordinates in FITS -
 Time and relative dimension in space",
Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
```

Repairs effected by these routines range from the translation of non-standard values for standard WCS keywords, to the repair of malformed coordinate representations. Some routines are also provided to check the consistency of pairs of keyvalues that define the same measure in two different ways, for example, as a date and an MJD.

A separate routine, wcspcx(), "regularizes" the linear transformation matrix component (PCi_j) of the coordinate transformation to make it more human- readable. Where a coordinate description was constructed from CDi_j, it decomposes it into PCi_j + CDELTi in a meaningful way. Optionally, it can also diagonalize the PCi_j matrix (as far as possible), i.e. undo a transposition of axes in the intermediate pixel coordinate system.

Non-standard keyvalues:
AIPS-convention celestial projection types, **NCP** and **GLS**, and spectral types, **'FREQ-LSR'**, **'FELO-HEL'**, etc., set in **CTYPE**ia are translated on-the-fly by wcsset() but without modifying the relevant ctype[], pv[] or specsys members of the wcsprm struct. That is, only the information extracted from ctype[] is translated when wcsset() fills in wcsprm::cel (celprm struct) or wcsprm::spc (spcprm struct).

On the other hand, these routines do change the values of wcsprm::ctype[], wcsprm::pv[], wcsprm::specsys and other wcsprm struct members as appropriate to produce the same result as if the FITS header itself had been translated.

Auxiliary WCS header information not used directly by WCSLIB may also be translated. For example, the older **DATE-OBS** date format (wcsprm::dateobs) is recast to year-2000 standard form, and **MJD-OBS** (wcsprm::mjdobs) will be deduced from it if not already set.

Certain combinations of keyvalues that result in malformed coordinate systems, as described in Sect. 7.3.4 of Paper I, may also be repaired. These are handled by cylfix().

Non-standard keywords:
The AIPS-convention CROTAn keywords are recognized as quasi-standard and as such are accomodated by wcsprm::crota[] and translated to wcsprm::pc[][] by wcsset(). These are not dealt with here, nor are any other non-standard keywords since these routines work only on the contents of a wcsprm struct and do not deal with FITS headers per se. In particular, they do not identify or translate **CD00i00j**, **PC00i00j**, **PROJPn**, **EPOCH**, **VELREF** or **VSOURCEa** keywords; this may be done by the FITS WCS header parser supplied with WCSLIB, refer to wcshdr.h.

wcsfix() and wcsfixi() apply all of the corrections handled by the following specific functions, which may also be invoked separately:

- cdfix(): Sets the diagonal element of the **CD**i_ja matrix to 1.0 if all **CD**i_ja keywords associated with a particular axis are omitted.
- datfix(): recast an older **DATE-OBS** date format in dateobs to year-2000 standard form. Derive dateref from mjdref if not already set. Alternatively, if dateref is set and mjdref isn't, then derive mjdref from it. If both are set, then check consistency. Likewise for dateobs and mjdobs; datebeg and mjdbeg; dateavg and mjdavg; and dateend and mjdend.
- obsfix(): if only one half of obsgeo[] is set, then derive the other half from it. If both halves are set, then check consistency.
- unitfix(): translate some commonly used but non-standard unit strings in the **CUNIT**ia keyvalues, e.g. '**DEG**' -> '**deg**'.
- spcfix(): translate AIPS-convention spectral types, **'FREQ-LSR'**, **'FELO-HEL'**, etc., in ctype[] as set from **CTYPE**ia.
- celfix(): translate AIPS-convention celestial projection types, **NCP** and **GLS**, in ctype[] as set from **CTYPE**ia.
- cylfix(): fixes WCS keyvalues for malformed cylindrical projections that suffer from the problem described in Sect. 7.3.4 of Paper I.

6.27.4 Function Documentation

wcsfix()

```
int wcsfix (
            int ctrl,
```

```
            const int naxis[],
            struct wcsprm * wcs,
            int stat[] )
```

Translate a non-standard WCS struct.

wcsfix() is identical to **wcsfixi**(), but lacks the info argument.

wcsfixi()

```
int wcsfixi (
            int ctrl,
            const int naxis[],
            struct wcsprm * wcs,
            int stat[],
            struct wcserr info[] )
```

Translate a non-standard WCS struct.

wcsfixi() applies all of the corrections handled separately by cdfix(), datfix(), obsfix(), unitfix(), spcfix(), celfix(), and cylfix().

Parameters

in	*ctrl*	Do potentially unsafe translations of non-standard unit strings as described in the usage notes to wcsutrn().
in	*naxis*	Image axis lengths. If this array pointer is set to zero then cylfix() will not be invoked.
in,out	*wcs*	Coordinate transformation parameters.
out	*stat*	Status returns from each of the functions. Use the preprocessor macros NWCSFIX to dimension this vector and CDFIX, DATFIX, **OBS**FIX, UNITFIX, SPCFIX, CELFIX, and CYLFIX to access its elements. A status value of -2 is set for functions that were not invoked.
out	*info*	Status messages from each of the functions. Use the preprocessor macros NWCSFIX to dimension this vector and CDFIX, DATFIX, **OBS**FIX, UNITFIX, SPCFIX, CELFIX, and CYLFIX to access its elements. Note that the memory allocated by **wcsfixi**() for the message in each wcserr struct (wcserr::msg, if non-zero) must be freed by the user. See wcsdealloc().

Returns

Status return value:

- 0: Success.
- 1: One or more of the translation functions returned an error.

cdfix()

```
int cdfix (
            struct wcsprm * wcs )
```

Fix erroneously omitted **CD**i_ja keywords.

cdfix() sets the diagonal element of the **CD**i_ja matrix to unity if all **CD**i_ja keywords associated with a given axis were omitted. According to WCS Paper I, if any **CD**i_ja keywords at all are given in a FITS header then those not given default to zero. This results in a singular matrix with an intersecting row and column of zeros.

cdfix() is expected to be invoked before wcsset(), which will fail if these errors have not been corrected.

Parameters

in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.

datfix()

```
int datfix (
              struct wcsprm * wcs )
```

Translate **DATE-OBS** and derive **MJD-OBS** or vice versa.

datfix() translates the old **DATE-OBS** date format set in wcsprm::dateobs to year-2000 standard form (*yyyy-mm-dd***T***hh:mm:ss*). It derives wcsprm::dateref from wcsprm::mjdref if not already set. Alternatively, if dateref is set and mjdref isn't, then it derives mjdref from it. If both are set but disagree by more than 0.001 day (86.4 seconds) then an error status is returned. Likewise for wcsprm::dateobs and wcsprm::mjdobs; wcsprm::datebeg and wcsprm::mjdbeg; wcsprm::dateavg and wcsprm::mjdavg; and wcsprm::dateend and wcsprm::mjdend.

If neither dateobs nor mjdobs are set, but wcsprm::jepoch (primarily) or wcsprm::bepoch is, then both are derived from it. If jepoch and/or bepoch are set but disagree with dateobs or mjdobs by more than 0.000002 year (63.2 seconds), an informative message is produced.

The translations done by **datfix**() do not affect and are not affected by wcsset().

Parameters

in,out	*wcs*	Coordinate transformation parameters. wcsprm::dateref and/or wcsprm::mjdref may be changed. wcsprm::dateobs and/or wcsprm::mjdobs may be changed. wcsprm::datebeg and/or wcsprm::mjdbeg may be changed. wcsprm::dateavg and/or wcsprm::mjdavg may be changed. wcsprm::dateend and/or wcsprm::mjdend may be changed.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 5: Invalid parameter value.

For returns >= 0, a detailed message, whether informative or an error message, may be set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_DATE_FIX.

Notes:

1. The MJD algorithms used by **datfix**() are from D.A. Hatcher, 1984, QJRAS, 25, 53-55, as modified by P.T. Wallace for use in SLALIB subroutines *CLDJ* and *DJCL*.

obsfix()

```
int obsfix (
              int ctrl,
              struct wcsprm * wcs )
```

complete the **OBS**GEO-[XYZLBH] vector of observatory coordinates.

obsfix() completes the wcsprm::obsgeo vector of observatory coordinates. That is, if only the (x,y,z) Cartesian coordinate triplet or the (l,b,h) geodetic coordinate triplet are set, then it derives the other triplet from it. If both triplets are set, then it checks for consistency at the level of 1 metre.

The operations done by **obsfix**() do not affect and are not affected by wcsset().

Parameters

in	*ctrl*	Flag that controls behaviour if one triplet is defined and the other is only partially defined: • 0: Reset only the undefined elements of an incomplete coordinate triplet. • 1: Reset all elements of an incomplete triplet. • 2: Don't make any changes, check for consistency only. Returns an error if either of the two triplets is incomplete.
in,out	*wcs*	Coordinate transformation parameters. wcsprm::obsgeo may be changed.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 5: Invalid parameter value.

For returns >= 0, a detailed message, whether informative or an error message, may be set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_**OBS**_FIX.

Notes:

1. While the International Terrestrial Reference System (ITRS) is based solely on Cartesian coordinates, it recommends the use of the GRS80 ellipsoid in converting to geodetic coordinates. However, while WCS Paper III recommends ITRS Cartesian coordinates, Paper VII prescribes the use of the IAU(1976) ellipsoid for geodetic coordinates, and consequently that is what is used here.
2. For reference, parameters of commonly used global reference ellipsoids:

a (m)	1/f	Standard
6378140	298.2577	IAU(1976)
6378137	298.257222101	GRS80
6378137	298.257223563	WGS84
6378136	298.257	IERS(1989)
6378136.6	298.25642	IERS(2003,2010), IAU(2009/2012)

where f = (a - b) / a is the flattening, and a and b are the semi-major and semi-minor radii in metres.

3. The transformation from geodetic (lng,lat,hgt) to Cartesian (x,y,z) is

```
x = (n + hgt)*coslng*coslat,
y = (n + hgt)*sinlng*coslat,
z = (n*(1.0 - e^2) + hgt)*sinlat,
```

where the "prime vertical radius", n, is a function of latitude

```
n = a / sqrt(1 - (e*sinlat)^2),
```

and a, the equatorial radius, and e^2 = (2 - f)*f, the (first) eccentricity of the ellipsoid, are constants. **obsfix**() inverts these iteratively by writing

```
   x = rho*coslng*coslat,
   y = rho*sinlng*coslat,
zeta = rho*sinlat,
```

where

```
 rho = n + hgt,
     = sqrt(x^2 + y^2 + zeta^2),
zeta = z / (1 - n*e^2/rho),
```

and iterating over the value of zeta. Since e is small, a good first approximation is given by zeta = z.

unitfix()

```
int unitfix (
             int ctrl,
             struct wcsprm * wcs )
```

Correct aberrant **CUNIT**ia keyvalues.

unitfix() applies wcsutrn() to translate non-standard **CUNIT**ia keyvalues, e.g. '**DEG**' -> '**deg**', also stripping off unnecessary whitespace.

unitfix() is expected to be invoked before wcsset(), which will fail if non-standard **CUNIT**ia keyvalues have not been translated.

Parameters

in	*ctrl*	Do potentially unsafe translations described in the usage notes to wcsutrn().
in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success (an alias was applied).
- 1: Null wcsprm pointer passed.

When units are translated (i.e. 0 is returned), an informative message is set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_UNITS_ALIAS.

spcfix()

```
int spcfix (
             struct wcsprm * wcs )
```

Translate AIPS-convention spectral types.

spcfix() translates AIPS-convention spectral coordinate types, '{**FREQ**,**FELO**,**VELO**}-{**LSR**,**HEL**,**OBS**}' (e.g. 'FREQ-OBS', **'FELO-HEL'**, 'VELO-LSR') set in wcsprm::ctype[], subject to **VELREF** set in wcsprm::velref.

Note that if wcs::specsys is already set then it will not be overridden.

AIPS-convention spectral types set in **CTYPE**ia are translated on-the-fly by wcsset() but without modifying wcsprm::ctype[] or wcsprm::specsys. That is, only the information extracted from wcsprm::ctype[] is translated when wcsset() fills in wcsprm::spc (spcprm struct). **spcfix**() modifies wcsprm::ctype[] so that if the header is subsequently written out, e.g. by wcshdo(), then it will contain translated **CTYPE**ia keyvalues.

The operations done by **spcfix**() do not affect and are not affected by wcsset().

Parameters

in,out	*wcs*	Coordinate transformation parameters. wcsprm::ctype[] and/or wcsprm::specsys may be changed.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns >= 0, a detailed message, whether informative or an error message, may be set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_SPC_UPDTE.

celfix()

```
int celfix (
            struct wcsprm * wcs )
```

Translate AIPS-convention celestial projection types.

celfix() translates AIPS-convention celestial projection types, **NCP** and **GLS**, set in the ctype[] member of the wcsprm struct.

Two additional pv[] keyvalues are created when translating **NCP**, and three are created when translating **GLS** with non-zero reference point. If the pv[] array was initially allocated by wcsini() then the array will be expanded if necessary. Otherwise, error 2 will be returned if sufficient empty slots are not already available for use.

AIPS-convention celestial projection types set in **CTYPE**ia are translated on-the-fly by wcsset() but without modifying wcsprm::ctype[], wcsprm::pv[], or wcsprm::npv. That is, only the information extracted from wcsprm::ctype[] is translated when wcsset() fills in wcsprm::cel (celprm struct). **celfix**() modifies wcsprm::ctype[], wcsprm::pv[], and wcsprm::npv so that if the header is subsequently written out, e.g. by wcshdo(), then it will contain translated **CTYPE**ia keyvalues and the relevant **PV**i_ma.

The operations done by **celfix**() do not affect and are not affected by wcsset(). However, it uses information in the wcsprm struct provided by wcsset(), and will invoke it if necessary.

Parameters

in,out	*wcs*	Coordinate transformation parameters. wcsprm::ctype[] and/or wcsprm::pv[] may be changed.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

cylfix()

```
int cylfix (
             const int naxis[],
             struct wcsprm * wcs )
```

Fix malformed cylindrical projections.

cylfix() fixes WCS keyvalues for malformed cylindrical projections that suffer from the problem described in Sect. 7.3.4 of Paper I.

cylfix() requires the wcsprm struct to have been set up by wcsset(), and will invoke it if necessary. After modification, the struct is reset on return with an explicit call to wcsset().

Parameters

in	*naxis*	Image axis lengths.
in,out	*wcs*	Coordinate transformation parameters.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.

- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 8: All of the corner pixel coordinates are invalid.
- 9: Could not determine reference pixel coordinate.
- 10: Could not determine reference pixel value.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcspcx()

```
int wcspcx (
              struct wcsprm * wcs,
              int dopc,
              int permute,
              double rotn[2] )
```

regularize PCi_j.

wcspcx() "regularizes" the linear transformation matrix component of the coordinate transformation (**PC**i_ja) to make it more human-readable.

Normally, upon encountering a FITS header containing a **CD**i_ja matrix, wcsset() simply treats it as **PC**i_ja and sets **CDELT**ia to unity. However, **wcspcx**() decomposes **CD**i_ja into **PC**i_ja and **CDELT**ia in such a way that **CDELT**ia form meaningful scaling parameters. In practice, the residual **PC**i_ja matrix will often then be orthogonal, i.e. unity, or describing a pure rotation, axis permutation, or reflection, or a combination thereof.

The decomposition is based on normalizing the length in the transformed system (i.e. intermediate pixel coordinates) of the orthonormal basis vectors of the pixel coordinate system. This deviates slightly from the prescription given by Eq. (4) of WCS Paper I, namely Sum(j=1,N)(**PC**i_ja)^2 = 1, in replacing the sum over j with the sum over i. Consequently, the columns of **PC**i_ja will consist of unit vectors. In practice, especially in cubes and higher dimensional images, at least some pairs of these unit vectors, if not all, will often be orthogonal or close to orthogonal.

The sign of **CDELT**ia is chosen to make the **PC**i_ja matrix as close to the, possibly permuted, unit matrix as possible, except that where the coordinate description contains a pair of celestial axes, the sign of **CDELT**ia is set negative for the longitude axis and positive for the latitude axis.

Optionally, rows of the **PC**i_ja matrix may also be permuted to diagonalize it as far as possible, thus undoing any transposition of axes in the intermediate pixel coordinate system.

If the coordinate description contains a celestial plane, then the angle of rotation of each of the basis vectors associated with the celestial axes is returned. For a pure rotation the two angles should be identical. Any difference between them is a measure of axis skewness.

The decomposition is not performed for axes involving a sequent distortion function that is defined in terms of **CD**i_ja, such as TPV, TNX, or ZPX, which always are. The independent variables of the polynomial are therefore intermediate world coordinates rather than intermediate pixel coordinates. Because sequent distortions are always applied before **CDELT**ia, if **CD**i_ja was translated to **PC**i_ja plus **CDELT**ia, then the distortion would be altered unless the polynomial coefficients were also adjusted to account for the change of scale.

wcspcx() requires the wcsprm struct to have been set up by wcsset(), and will invoke it if necessary. The wcsprm struct is reset on return with an explicit call to wcsset().

Parameters

in,out	*wcs*	Coordinate transformation parameters.
in	*dopc*	If 1, then **PC**i_ja and **CDELT**ia, as given, will be recomposed according to the above prescription. If 0, the operation is restricted to decomposing **CD**i_ja.
in	*permute*	If 1, then after decomposition (or recomposition), permute rows of **PC**i_ja to make the axes of the intermediate pixel coordinate system match as closely as possible those of the pixel coordinates. That is, make it as close to a diagonal matrix as possible. However, celestial axes are special in always being paired, with the longitude axis preceding the latitude axis. All WCS entities indexed by i, such as **CTYPE**ia, **CRVAL**ia, **CDELT**ia, etc., including coordinate lookup tables, will also be permuted as necessary to account for the change to **PC**i_ja. This does not apply to **CRPIX**ja, nor prior distortion functions. These operate on pixel coordinates, which are not affected by the permutation.
out	*rotn*	with the celestial axes. For a pure rotation the two angles should be identical. Any difference between them is a measure of axis skewness. May be set to the NULL pointer if this information is not required.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 5: CDi_j matrix not used.
- 6: Sequent distortion function present.

6.27.5 Variable Documentation

00023 *===========================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wcsfix routines
00031 * ------------------------------
00032 * Routines in this suite identify and translate various forms of construct
00033 * known to occur in FITS headers that violate the FITS World Coordinate System
00034 * (WCS) standard described in
00035 *
00036 =   "Representations of world coordinates in FITS",
00037 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00038 =
00039 =   "Representations of celestial coordinates in FITS",
00040 =   Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
00041 =
00042 =   "Representations of spectral coordinates in FITS",
00043 =   Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00044 =   2006, A&A, 446, 747 (WCS Paper III)
00045 =
00046 =   "Representations of time coordinates in FITS -
00047 =    Time and relative dimension in space",
00048 =   Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
00049 =   Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
00050 *
00051 * Repairs effected by these routines range from the translation of
00052 * non-standard values for standard WCS keywords, to the repair of malformed
00053 * coordinate representations.  Some routines are also provided to check the
00054 * consistency of pairs of keyvalues that define the same measure in two
00055 * different ways, for example, as a date and an MJD.
00056 *
00057 * A separate routine, wcspcx(), "regularizes" the linear transformation matrix
00058 * component (PCi_j) of the coordinate transformation to make it more human-
00059 * readable.  Where a coordinate description was constructed from CDi_j, it
00060 * decomposes it into PCi_j + CDELTi in a meaningful way.  Optionally, it can
00061 * also diagonalize the PCi_j matrix (as far as possible), i.e. undo a
00062 * transposition of axes in the intermediate pixel coordinate system.
00063 *
00064 * Non-standard keyvalues:
00065 * -----------------------
00066 *   AIPS-convention celestial projection types, NCP and GLS, and spectral
00067 *   types, 'FREQ-LSR', 'FELO-HEL', etc., set in CTYPEia are translated
00068 *   on-the-fly by wcsset() but without modifying the relevant ctype[], pv[] or
00069 *   specsys members of the wcsprm struct.  That is, only the information
00070 *   extracted from ctype[] is translated when wcsset() fills in wcsprm::cel
00071 *   (celprm struct) or wcsprm::spc (spcprm struct).
00072 *
00073 *   On the other hand, these routines do change the values of wcsprm::ctype[],
00074 *   wcsprm::pv[], wcsprm::specsys and other wcsprm struct members as
00075 *   appropriate to produce the same result as if the FITS header itself had
00076 *   been translated.
00077 *
00078 *   Auxiliary WCS header information not used directly by WCSLIB may also be
00079 *   translated.  For example, the older DATE-OBS date format (wcsprm::dateobs)
00080 *   is recast to year-2000 standard form, and MJD-OBS (wcsprm::mjdobs) will be
00081 *   deduced from it if not already set.
00082 *
00083 *   Certain combinations of keyvalues that result in malformed coordinate
00084 *   systems, as described in Sect. 7.3.4 of Paper I, may also be repaired.
00085 *   These are handled by cylfix().
00086 *
00087 * Non-standard keywords:
00088 * ----------------------
00089 *   The AIPS-convention CROTAn keywords are recognized as quasi-standard
00090 *   and as such are accomodated by wcsprm::crota[] and translated to
00091 *   wcsprm::pc[][] by wcsset().  These are not dealt with here, nor are any
00092 *   other non-standard keywords since these routines work only on the contents
00093 *   of a wcsprm struct and do not deal with FITS headers per se.  In
00094 *   particular, they do not identify or translate CD00i00j, PC00i00j, PROJPn,
00095 *   EPOCH, VELREF or VSOURCEa keywords; this may be done by the FITS WCS
00096 *   header parser supplied with WCSLIB, refer to wcshdr.h.
00097 *
00098 * wcsfix() and wcsfixi() apply all of the corrections handled by the following
00099 * specific functions, which may also be invoked separately:
00100 *
00101 *   - cdfix(): Sets the diagonal element of the CDi_ja matrix to 1.0 if all
```

```
00102 *     CDi_ja keywords associated with a particular axis are omitted.
00103 *
00104 *   - datfix(): recast an older DATE-OBS date format in dateobs to year-2000
00105 *     standard form.  Derive dateref from mjdref if not already set.
00106 *     Alternatively, if dateref is set and mjdref isn't, then derive mjdref
00107 *     from it.  If both are set, then check consistency.  Likewise for dateobs
00108 *     and mjdobs; datebeg and mjdbeg; dateavg and mjdavg; and dateend and
00109 *     mjdend.
00110 *
00111 *   - obsfix(): if only one half of obsgeo[] is set, then derive the other
00112 *     half from it.  If both halves are set, then check consistency.
00113 *
00114 *   - unitfix(): translate some commonly used but non-standard unit strings in
00115 *     the CUNITia keyvalues, e.g. 'DEG' -> 'deg'.
00116 *
00117 *   - spcfix(): translate AIPS-convention spectral types, 'FREQ-LSR',
00118 *     'FELO-HEL', etc., in ctype[] as set from CTYPEia.
00119 *
00120 *   - celfix(): translate AIPS-convention celestial projection types, NCP and
00121 *     GLS, in ctype[] as set from CTYPEia.
00122 *
00123 *   - cylfix(): fixes WCS keyvalues for malformed cylindrical projections that
00124 *     suffer from the problem described in Sect. 7.3.4 of Paper I.
00125 *
00126 *
00127 * wcsfix() - Translate a non-standard WCS struct
00128 * ----------------------------------------------
00129 * wcsfix() is identical to wcsfixi(), but lacks the info argument.
00130 *
00131 *
00132 * wcsfixi() - Translate a non-standard WCS struct
00133 * -----------------------------------------------
00134 * wcsfixi() applies all of the corrections handled separately by cdfix(),
00135 * datfix(), obsfix(), unitfix(), spcfix(), celfix(), and cylfix().
00136 *
00137 * Given:
00138 *   ctrl      int       Do potentially unsafe translations of non-standard
00139 *                       unit strings as described in the usage notes to
00140 *                       wcsutrn().
00141 *
00142 *   naxis     const int []
00143 *                       Image axis lengths.  If this array pointer is set to
00144 *                       zero then cylfix() will not be invoked.
00145 *
00146 * Given and returned:
00147 *   wcs       struct wcsprm*
00148 *                       Coordinate transformation parameters.
00149 *
00150 * Returned:
00151 *   stat      int [NWCSFIX]
00152 *                       Status returns from each of the functions.  Use the
00153 *                       preprocessor macros NWCSFIX to dimension this vector
00154 *                       and CDFIX, DATFIX, OBSFIX, UNITFIX, SPCFIX, CELFIX,
00155 *                       and CYLFIX to access its elements.  A status value
00156 *                       of -2 is set for functions that were not invoked.
00157 *
00158 *   info      struct wcserr [NWCSFIX]
00159 *                       Status messages from each of the functions.  Use the
00160 *                       preprocessor macros NWCSFIX to dimension this vector
00161 *                       and CDFIX, DATFIX, OBSFIX, UNITFIX, SPCFIX, CELFIX,
00162 *                       and CYLFIX to access its elements.
00163 *
00164 *                       Note that the memory allocated by wcsfixi() for the
00165 *                       message in each wcserr struct (wcserr::msg, if
00166 *                       non-zero) must be freed by the user.  See
00167 *                       wcsdealloc().
00168 *
00169 * Function return value:
00170 *             int       Status return value:
00171 *                         0: Success.
00172 *                         1: One or more of the translation functions
00173 *                            returned an error.
00174 *
00175 *
00176 * cdfix() - Fix erroneously omitted CDi_ja keywords
00177 * ------------------------------------------------
00178 * cdfix() sets the diagonal element of the CDi_ja matrix to unity if all
00179 * CDi_ja keywords associated with a given axis were omitted.  According to WCS
00180 * Paper I, if any CDi_ja keywords at all are given in a FITS header then those
00181 * not given default to zero.  This results in a singular matrix with an
00182 * intersecting row and column of zeros.
00183 *
00184 * cdfix() is expected to be invoked before wcsset(), which will fail if these
00185 * errors have not been corrected.
00186 *
00187 * Given and returned:
00188 *   wcs       struct wcsprm*
```

```
00189 *                      Coordinate transformation parameters.
00190 *
00191 * Function return value:
00192 *             int      Status return value:
00193 *                        -1: No change required (not an error).
00194 *                         0: Success.
00195 *                         1: Null wcsprm pointer passed.
00196 *
00197 *
00198 * datfix() - Translate DATE-OBS and derive MJD-OBS or vice versa
00199 * ---------------------------------------------------------------
00200 * datfix() translates the old DATE-OBS date format set in wcsprm::dateobs to
00201 * year-2000 standard form (yyyy-mm-ddThh:mm:ss).  It derives wcsprm::dateref
00202 * from wcsprm::mjdref if not already set.  Alternatively, if dateref is set
00203 * and mjdref isn't, then it derives mjdref from it.  If both are set but
00204 * disagree by more than 0.001 day (86.4 seconds) then an error status is
00205 * returned.  Likewise for wcsprm::dateobs and wcsprm::mjdobs; wcsprm::datebeg
00206 * and wcsprm::mjdbeg; wcsprm::dateavg and wcsprm::mjdavg; and wcsprm::dateend
00207 * and wcsprm::mjdend.
00208 *
00209 * If neither dateobs nor mjdobs are set, but wcsprm::jepoch (primarily) or
00210 * wcsprm::bepoch is, then both are derived from it.  If jepoch and/or bepoch
00211 * are set but disagree with dateobs or mjdobs by more than 0.000002 year
00212 * (63.2 seconds), an informative message is produced.
00213 *
00214 * The translations done by datfix() do not affect and are not affected by
00215 * wcsset().
00216 *
00217 * Given and returned:
00218 *   wcs       struct wcsprm*
00219 *                      Coordinate transformation parameters.
00220 *                      wcsprm::dateref and/or wcsprm::mjdref may be changed.
00221 *                      wcsprm::dateobs and/or wcsprm::mjdobs may be changed.
00222 *                      wcsprm::datebeg and/or wcsprm::mjdbeg may be changed.
00223 *                      wcsprm::dateavg and/or wcsprm::mjdavg may be changed.
00224 *                      wcsprm::dateend and/or wcsprm::mjdend may be changed.
00225 *
00226 * Function return value:
00227 *             int      Status return value:
00228 *                        -1: No change required (not an error).
00229 *                         0: Success.
00230 *                         1: Null wcsprm pointer passed.
00231 *                         5: Invalid parameter value.
00232 *
00233 *                      For returns >= 0, a detailed message, whether
00234 *                      informative or an error message, may be set in
00235 *                      wcsprm::err if enabled, see wcserr_enable(), with
00236 *                      wcsprm::err.status set to FIXERR_DATE_FIX.
00237 *
00238 * Notes:
00239 *   1: The MJD algorithms used by datfix() are from D.A. Hatcher, 1984, QJRAS,
00240 *      25, 53-55, as modified by P.T. Wallace for use in SLALIB subroutines
00241 *      CLDJ and DJCL.
00242 *
00243 *
00244 * obsfix() - complete the OBSGEO-[XYZLBH] vector of observatory coordinates
00245 * -------------------------------------------------------------------------
00246 * obsfix() completes the wcsprm::obsgeo vector of observatory coordinates.
00247 * That is, if only the (x,y,z) Cartesian coordinate triplet or the (l,b,h)
00248 * geodetic coordinate triplet are set, then it derives the other triplet from
00249 * it.  If both triplets are set, then it checks for consistency at the level
00250 * of 1 metre.
00251 *
00252 * The operations done by obsfix() do not affect and are not affected by
00253 * wcsset().
00254 *
00255 * Given:
00256 *   ctrl      int      Flag that controls behaviour if one triplet is
00257 *                      defined and the other is only partially defined:
00258 *                        0: Reset only the undefined elements of an
00259 *                           incomplete coordinate triplet.
00260 *                        1: Reset all elements of an incomplete triplet.
00261 *                        2: Don't make any changes, check for consistency
00262 *                           only.  Returns an error if either of the two
00263 *                           triplets is incomplete.
00264 *
00265 * Given and returned:
00266 *   wcs       struct wcsprm*
00267 *                      Coordinate transformation parameters.
00268 *                      wcsprm::obsgeo may be changed.
00269 *
00270 * Function return value:
00271 *             int      Status return value:
00272 *                        -1: No change required (not an error).
00273 *                         0: Success.
00274 *                         1: Null wcsprm pointer passed.
00275 *                         5: Invalid parameter value.
```

```
00276 *
00277 *                       For returns >= 0, a detailed message, whether
00278 *                       informative or an error message, may be set in
00279 *                       wcsprm::err if enabled, see wcserr_enable(), with
00280 *                       wcsprm::err.status set to FIXERR_OBS_FIX.
00281 *
00282 * Notes:
00283 *   1: While the International Terrestrial Reference System (ITRS) is based
00284 *      solely on Cartesian coordinates, it recommends the use of the GRS80
00285 *      ellipsoid in converting to geodetic coordinates.  However, while WCS
00286 *      Paper III recommends ITRS Cartesian coordinates, Paper VII prescribes
00287 *      the use of the IAU(1976) ellipsoid for geodetic coordinates, and
00288 *      consequently that is what is used here.
00289 *
00290 *   2: For reference, parameters of commonly used global reference ellipsoids:
00291 *
00292 =          a (m)          1/f                    Standard
00293 =        ---------  -------------  --------------------------------
00294 =        6378140    298.2577        IAU(1976)
00295 =        6378137    298.257222101   GRS80
00296 =        6378137    298.257223563   WGS84
00297 =        6378136    298.257         IERS(1989)
00298 =        6378136.6  298.25642       IERS(2003,2010), IAU(2009/2012)
00299 *
00300 *      where f = (a - b) / a is the flattening, and a and b are the semi-major
00301 *      and semi-minor radii in metres.
00302 *
00303 *   3: The transformation from geodetic (lng,lat,hgt) to Cartesian (x,y,z) is
00304 *
00305 =        x = (n + hgt)*coslng*coslat,
00306 =        y = (n + hgt)*sinlng*coslat,
00307 =        z = (n*(1.0 - e^2) + hgt)*sinlat,
00308 *
00309 *      where the "prime vertical radius", n, is a function of latitude
00310 *
00311 =        n = a / sqrt(1 - (e*sinlat)^2),
00312 *
00313 *      and a, the equatorial radius, and e^2 = (2 - f)*f, the (first)
00314 *      eccentricity of the ellipsoid, are constants.  obsfix() inverts these
00315 *      iteratively by writing
00316 *
00317 =            x = rho*coslng*coslat,
00318 =            y = rho*sinlng*coslat,
00319 =          zeta = rho*sinlat,
00320 *
00321 *      where
00322 *
00323 =           rho = n + hgt,
00324 =               = sqrt(x^2 + y^2 + zeta^2),
00325 =          zeta = z / (1 - n*e^2/rho),
00326 *
00327 *      and iterating over the value of zeta.  Since e is small, a good first
00328 *      approximation is given by zeta = z.
00329 *
00330 *
00331 * unitfix() - Correct aberrant CUNITia keyvalues
00332 * ----------------------------------------------
00333 * unitfix() applies wcsutrn() to translate non-standard CUNITia keyvalues,
00334 * e.g. 'DEG' -> 'deg', also stripping off unnecessary whitespace.
00335 *
00336 * unitfix() is expected to be invoked before wcsset(), which will fail if
00337 * non-standard CUNITia keyvalues have not been translated.
00338 *
00339 * Given:
00340 *   ctrl      int       Do potentially unsafe translations described in the
00341 *                       usage notes to wcsutrn().
00342 *
00343 * Given and returned:
00344 *   wcs       struct wcsprm*
00345 *                       Coordinate transformation parameters.
00346 *
00347 * Function return value:
00348 *             int       Status return value:
00349 *                         -1: No change required (not an error).
00350 *                          0: Success (an alias was applied).
00351 *                          1: Null wcsprm pointer passed.
00352 *
00353 *                       When units are translated (i.e. 0 is returned), an
00354 *                       informative message is set in wcsprm::err if enabled,
00355 *                       see wcserr_enable(), with wcsprm::err.status set to
00356 *                       FIXERR_UNITS_ALIAS.
00357 *
00358 *
00359 * spcfix() - Translate AIPS-convention spectral types
00360 * ---------------------------------------------------
00361 * spcfix() translates AIPS-convention spectral coordinate types,
00362 * '{FREQ,FELO,VELO}-{LSR,HEL,OBS}' (e.g. 'FREQ-OBS', 'FELO-HEL', 'VELO-LSR')
```

```
00363 * set in wcsprm::ctype[], subject to VELREF set in wcsprm::velref.
00364 *
00365 * Note that if wcs::specsys is already set then it will not be overridden.
00366 *
00367 * AIPS-convention spectral types set in CTYPEia are translated on-the-fly by
00368 * wcsset() but without modifying wcsprm::ctype[] or wcsprm::specsys.  That is,
00369 * only the information extracted from wcsprm::ctype[] is translated when
00370 * wcsset() fills in wcsprm::spc (spcprm struct).  spcfix() modifies
00371 * wcsprm::ctype[] so that if the header is subsequently written out, e.g. by
00372 * wcshdo(), then it will contain translated CTYPEia keyvalues.
00373 *
00374 * The operations done by spcfix() do not affect and are not affected by
00375 * wcsset().
00376 *
00377 * Given and returned:
00378 *   wcs       struct wcsprm*
00379 *                       Coordinate transformation parameters.  wcsprm::ctype[]
00380 *                       and/or wcsprm::specsys may be changed.
00381 *
00382 * Function return value:
00383 *             int       Status return value:
00384 *                        -1: No change required (not an error).
00385 *                         0: Success.
00386 *                         1: Null wcsprm pointer passed.
00387 *                         2: Memory allocation failed.
00388 *                         3: Linear transformation matrix is singular.
00389 *                         4: Inconsistent or unrecognized coordinate axis
00390 *                            types.
00391 *                         5: Invalid parameter value.
00392 *                         6: Invalid coordinate transformation parameters.
00393 *                         7: Ill-conditioned coordinate transformation
00394 *                            parameters.
00395 *
00396 *                       For returns >= 0, a detailed message, whether
00397 *                       informative or an error message, may be set in
00398 *                       wcsprm::err if enabled, see wcserr_enable(), with
00399 *                       wcsprm::err.status set to FIXERR_SPC_UPDTE.
00400 *
00401 *
00402 * celfix() - Translate AIPS-convention celestial projection types
00403 * ---------------------------------------------------------------
00404 * celfix() translates AIPS-convention celestial projection types, NCP and
00405 * GLS, set in the ctype[] member of the wcsprm struct.
00406 *
00407 * Two additional pv[] keyvalues are created when translating NCP, and three
00408 * are created when translating GLS with non-zero reference point.  If the pv[]
00409 * array was initially allocated by wcsini() then the array will be expanded if
00410 * necessary.  Otherwise, error 2 will be returned if sufficient empty slots
00411 * are not already available for use.
00412 *
00413 * AIPS-convention celestial projection types set in CTYPEia are translated
00414 * on-the-fly by wcsset() but without modifying wcsprm::ctype[], wcsprm::pv[],
00415 * or wcsprm::npv.  That is, only the information extracted from
00416 * wcsprm::ctype[] is translated when wcsset() fills in wcsprm::cel (celprm
00417 * struct).  celfix() modifies wcsprm::ctype[], wcsprm::pv[], and wcsprm::npv
00418 * so that if the header is subsequently written out, e.g. by wcshdo(), then it
00419 * will contain translated CTYPEia keyvalues and the relevant PVi_ma.
00420 *
00421 * The operations done by celfix() do not affect and are not affected by
00422 * wcsset().  However, it uses information in the wcsprm struct provided by
00423 * wcsset(), and will invoke it if necessary.
00424 *
00425 * Given and returned:
00426 *   wcs       struct wcsprm*
00427 *                       Coordinate transformation parameters.  wcsprm::ctype[]
00428 *                       and/or wcsprm::pv[] may be changed.
00429 *
00430 * Function return value:
00431 *             int       Status return value:
00432 *                        -1: No change required (not an error).
00433 *                         0: Success.
00434 *                         1: Null wcsprm pointer passed.
00435 *                         2: Memory allocation failed.
00436 *                         3: Linear transformation matrix is singular.
00437 *                         4: Inconsistent or unrecognized coordinate axis
00438 *                            types.
00439 *                         5: Invalid parameter value.
00440 *                         6: Invalid coordinate transformation parameters.
00441 *                         7: Ill-conditioned coordinate transformation
00442 *                            parameters.
00443 *
00444 *                       For returns > 1, a detailed error message is set in
00445 *                       wcsprm::err if enabled, see wcserr_enable().
00446 *
00447 *
00448 * cylfix() - Fix malformed cylindrical projections
00449 * ------------------------------------------------
```

```
00450 * cylfix() fixes WCS keyvalues for malformed cylindrical projections that
00451 * suffer from the problem described in Sect. 7.3.4 of Paper I.
00452 *
00453 * cylfix() requires the wcsprm struct to have been set up by wcsset(), and
00454 * will invoke it if necessary.  After modification, the struct is reset on
00455 * return with an explicit call to wcsset().
00456 *
00457 * Given:
00458 *   naxis     const int []
00459 *                       Image axis lengths.
00460 *
00461 * Given and returned:
00462 *   wcs       struct wcsprm*
00463 *                       Coordinate transformation parameters.
00464 *
00465 * Function return value:
00466 *             int       Status return value:
00467 *                        -1: No change required (not an error).
00468 *                         0: Success.
00469 *                         1: Null wcsprm pointer passed.
00470 *                         2: Memory allocation failed.
00471 *                         3: Linear transformation matrix is singular.
00472 *                         4: Inconsistent or unrecognized coordinate axis
00473 *                            types.
00474 *                         5: Invalid parameter value.
00475 *                         6: Invalid coordinate transformation parameters.
00476 *                         7: Ill-conditioned coordinate transformation
00477 *                            parameters.
00478 *                         8: All of the corner pixel coordinates are invalid.
00479 *                         9: Could not determine reference pixel coordinate.
00480 *                        10: Could not determine reference pixel value.
00481 *
00482 *                       For returns > 1, a detailed error message is set in
00483 *                       wcsprm::err if enabled, see wcserr_enable().
00484 *
00485 *
00486 * wcspcx() - regularize PCi_j
00487 * ---------------------------
00488 * wcspcx() "regularizes" the linear transformation matrix component of the
00489 * coordinate transformation (PCi_ja) to make it more human-readable.
00490 *
00491 * Normally, upon encountering a FITS header containing a CDi_ja matrix,
00492 * wcsset() simply treats it as PCi_ja and sets CDELTia to unity.  However,
00493 * wcspcx() decomposes CDi_ja into PCi_ja and CDELTia in such a way that
00494 * CDELTia form meaningful scaling parameters.  In practice, the residual
00495 * PCi_ja matrix will often then be orthogonal, i.e. unity, or describing a
00496 * pure rotation, axis permutation, or reflection, or a combination thereof.
00497 *
00498 * The decomposition is based on normalizing the length in the transformed
00499 * system (i.e. intermediate pixel coordinates) of the orthonormal basis
00500 * vectors of the pixel coordinate system.  This deviates slightly from the
00501 * prescription given by Eq. (4) of WCS Paper I, namely Sum(j=1,N)(PCi_ja)^2 = 1,
00502 * in replacing the sum over j with the sum over i.  Consequently, the columns
00503 * of PCi_ja will consist of unit vectors.  In practice, especially in cubes
00504 * and higher dimensional images, at least some pairs of these unit vectors, if
00505 * not all, will often be orthogonal or close to orthogonal.
00506 *
00507 * The sign of CDELTia is chosen to make the PCi_ja matrix as close to the,
00508 * possibly permuted, unit matrix as possible, except that where the coordinate
00509 * description contains a pair of celestial axes, the sign of CDELTia is set
00510 * negative for the longitude axis and positive for the latitude axis.
00511 *
00512 * Optionally, rows of the PCi_ja matrix may also be permuted to diagonalize
00513 * it as far as possible, thus undoing any transposition of axes in the
00514 * intermediate pixel coordinate system.
00515 *
00516 * If the coordinate description contains a celestial plane, then the angle of
00517 * rotation of each of the basis vectors associated with the celestial axes is
00518 * returned.  For a pure rotation the two angles should be identical.  Any
00519 * difference between them is a measure of axis skewness.
00520 *
00521 * The decomposition is not performed for axes involving a sequent distortion
00522 * function that is defined in terms of CDi_ja, such as TPV, TNX, or ZPX, which
00523 * always are.  The independent variables of the polynomial are therefore
00524 * intermediate world coordinates rather than intermediate pixel coordinates.
00525 * Because sequent distortions are always applied before CDELTia, if CDi_ja was
00526 * translated to PCi_ja plus CDELTia, then the distortion would be altered
00527 * unless the polynomial coefficients were also adjusted to account for the
00528 * change of scale.
00529 *
00530 * wcspcx() requires the wcsprm struct to have been set up by wcsset(), and
00531 * will invoke it if necessary.  The wcsprm struct is reset on return with an
00532 * explicit call to wcsset().
00533 *
00534 * Given and returned:
00535 *   wcs       struct wcsprm*
00536 *                       Coordinate transformation parameters.
```

```
00537 *
00538 * Given:
00539 *   dopc      int       If 1, then PCi_ja and CDELTia, as given, will be
00540 *                       recomposed according to the above prescription.  If 0,
00541 *                       the operation is restricted to decomposing CDi_ja.
00542 *
00543 *   permute   int       If 1, then after decomposition (or recomposition),
00544 *                       permute rows of PCi_ja to make the axes of the
00545 *                       intermediate pixel coordinate system match as closely
00546 *                       as possible those of the pixel coordinates.  That is,
00547 *                       make it as close to a diagonal matrix as possible.
00548 *                       However, celestial axes are special in always being
00549 *                       paired, with the longitude axis preceding the latitude
00550 *                       axis.
00551 *
00552 *                       All WCS entities indexed by i, such as CTYPEia,
00553 *                       CRVALia, CDELTia, etc., including coordinate lookup
00554 *                       tables, will also be permuted as necessary to account
00555 *                       for the change to PCi_ja.  This does not apply to
00556 *                       CRPIXja, nor prior distortion functions.  These
00557 *                       operate on pixel coordinates, which are not affected
00558 *                       by the permutation.
00559 *
00560 * Returned:
00561 *   rotn      double[2] Rotation angle [deg] of each basis vector associated
00562 *                       with the celestial axes.  For a pure rotation the two
00563 *                       angles should be identical.  Any difference between
00564 *                       them is a measure of axis skewness.
00565 *
00566 *                       May be set to the NULL pointer if this information is
00567 *                       not required.
00568 *
00569 * Function return value:
00570 *             int       Status return value:
00571 *                         0: Success.
00572 *                         1: Null wcsprm pointer passed.
00573 *                         2: Memory allocation failed.
00574 *                         5: CDi_j matrix not used.
00575 *                         6: Sequent distortion function present.
00576 *
00577 *
00578 * Global variable: const char *wcsfix_errmsg[] - Status return messages
00579 * ---------------------------------------------------------------------
00580 * Error messages to match the status value returned from each function.
00581 *

Enumerations

- enum wcshdr_errmsg_enum {
  WCSHDRERR_SUCCESS = 0 , WCSHDRERR_NULL_POINTER = 1 , WCSHDRERR_MEMORY = 2 ,
  WCSHDRERR_BAD_COLUMN = 3 ,
  WCSHDRERR_PARSER = 4 , WCSHDRERR_BAD_TABULAR_PARAMS = 5 }

Functions

- int wcspih (char *header, int nkeyrec, int relax, int ctrl, int *nreject, int *nwcs, struct wcsprm **wcs)

  FITS WCS parser routine for image headers.
- int wcsbth (char *header, int nkeyrec, int relax, int ctrl, int keysel, int *colsel, int *nreject, int *nwcs, struct wcsprm **wcs)

  FITS WCS parser routine for binary table and image headers.
- int wcstab (struct wcsprm *wcs)

  Tabular construction routine.
- int wcsidx (int nwcs, struct wcsprm **wcs, int alts[27])

  Index alternate coordinate representations.
- int wcsbdx (int nwcs, struct wcsprm **wcs, int type, short alts[1000][28])

  Index alternate coordinate represention.
- int wcsvfree (int *nwcs, struct wcsprm **wcs)

  Free the array of wcsprm structs.
- int wcshdo (int ctrl, struct wcsprm *wcs, int *nkeyrec, char **header)

  Write out a wcsprm struct as a FITS header.

Variables

- const char * wcshdr_errmsg [ ]

  Status return messages.

6.29.1 Detailed Description

Routines in this suite are aimed at extracting WCS information from a FITS file. The information is encoded via keywords defined in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)

"Representations of distortions in FITS world coordinate systems",
Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
available from http://www.atnf.csiro.au/people/Mark.Calabretta

"Representations of time coordinates in FITS -
 Time and relative dimension in space",
Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
```

These routines provide the high-level interface between the FITS file and the WCS coordinate transformation routines.

Additionally, function wcshdo() is provided to write out the contents of a wcsprm struct as a FITS header.

Briefly, the anticipated sequence of operations is as follows:

- 1: Open the FITS file and read the image or binary table header, e.g. using CFITSIO routine *fits_hdr2str()*.
- 2: Parse the header using wcspih() or wcsbth(); they will automatically interpret **'TAB'** header keywords using wcstab().
- 3: Allocate memory for, and read **'TAB'** arrays from the binary table extension, e.g. using CFITSIO routine fits_read_wcstab() - refer to the prologue of getwcstab.h. wcsset() will automatically take control of this allocated memory, in particular causing it to be freed by wcsfree().
- 4: Translate non-standard WCS usage using wcsfix(), see wcsfix.h.
- 5: Initialize wcsprm struct(s) using wcsset() and calculate coordinates using wcsp2s() and/or wcss2p(). Refer to the prologue of wcs.h for a description of these and other high-level WCS coordinate transformation routines.
- 6: Clean up by freeing memory with wcsvfree().

In detail:

- wcspih() is a high-level FITS WCS routine that parses an image header. It returns an array of up to 27 wcsprm structs on each of which it invokes wcstab().
- wcsbth() is the analogue of wcspih() for use with binary tables; it handles image array and pixel list keywords. As an extension of the FITS WCS standard, it also recognizes image header keywords which may be used to provide default values via an inheritance mechanism.
- wcstab() assists in filling in members of the wcsprm struct associated with coordinate lookup tables (**'TAB'**). These are based on arrays stored in a FITS binary table extension (BINTABLE) that are located by **PV**i_ma keywords in the image header.
- wcsidx() and wcsbdx() are utility routines that return the index for a specified alternate coordinate descriptor in the array of wcsprm structs returned by wcspih() or wcsbth().
- wcsvfree() deallocates memory for an array of wcsprm structs, such as returned by wcspih() or wcsbth().
- wcshdo() writes out a wcsprm struct as a FITS header.

6.29.2 Macro Definition Documentation

WCSHDR_none

```
#define WCSHDR_none 0x00000000
```

Bit mask for wcspih() and wcsbth() - reject all extensions.

Bit mask for the *relax* argument of wcspih() and wcsbth() - reject all extensions.

Refer to wcsbth() note 5.

WCSHDR_all

```
#define WCSHDR_all 0x000FFFFF
```

Bit mask for wcspih() and wcsbth() - accept all extensions.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept all extensions.

Refer to wcsbth() note 5.

WCSHDR_reject

```
#define WCSHDR_reject 0x10000000
```

Bit mask for wcspih() and wcsbth() - reject non-standard keywords.

Bit mask for the *relax* argument of wcspih() and wcsbth() - reject non-standard keywords.

Refer to wcsbth() note 5.

WCSHDR_strict

```
#define WCSHDR_strict 0x20000000
```

WCSHDR_CROTAia

```
#define WCSHDR_CROTAia 0x00000001
```

Bit mask for wcspih() and wcsbth() - accept **CROTA**ia, i**CROT**na, **TCROT**na.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **CROTA**ia, i**CROT**na, **TCROT**na.

Refer to wcsbth() note 5.

WCSHDR_VELREFa

```
#define WCSHDR_VELREFa 0x00000002
```

Bit mask for wcspih() and wcsbth() - accept **VELREF**a.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **VELREF**a.

Refer to wcsbth() note 5.

WCSHDR_CD00i00j

```
#define WCSHDR_CD00i00j 0x00000004
```

Bit mask for wcspih() and wcsbth() - accept **CD00**i**00**j.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **CD00**i**00**j.

Refer to wcsbth() note 5.

WCSHDR_PC00i00j

```
#define WCSHDR_PC00i00j 0x00000008
```

Bit mask for wcspih() and wcsbth() - accept **PC00**i**00**j.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **PC00**i**00**j.

Refer to wcsbth() note 5.

WCSHDR_PROJPn

```
#define WCSHDR_PROJPn 0x00000010
```

Bit mask for wcspih() and wcsbth() - accept **PROJP**n.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **PROJP**n.

Refer to wcsbth() note 5.

WCSHDR_CD0i_0ja

```
#define WCSHDR_CD0i_0ja 0x00000020
```

WCSHDR_PC0i_0ja

```
#define WCSHDR_PC0i_0ja 0x00000040
```

WCSHDR_PV0i_0ma

```
#define WCSHDR_PV0i_0ma 0x00000080
```

WCSHDR_PS0i_0ma

```
#define WCSHDR_PS0i_0ma 0x00000100
```

WCSHDR_DOBSn

```
#define WCSHDR_DOBSn 0x00000200
```

Bit mask for wcspih() and wcsbth() - accept **DOBS**n.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **DOBS**n.

Refer to wcsbth() note 5.

WCSHDR_OBSGLBHn

```
#define WCSHDR_OBSGLBHn 0x00000400
```

WCSHDR_RADECSYS

```
#define WCSHDR_RADECSYS 0x00000800
```

Bit mask for wcspih() and wcsbth() - accept **RADECSYS**.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **RADECSYS**.

Refer to wcsbth() note 5.

WCSHDR_EPOCHa

```
#define WCSHDR_EPOCHa 0x00001000
```

Bit mask for wcspih() and wcsbth() - accept **EPOCH**a.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **EPOCH**a.

Refer to wcsbth() note 5.

WCSHDR_VSOURCE

```
#define WCSHDR_VSOURCE 0x00002000
```

Bit mask for wcspih() and wcsbth() - accept **VSOURCE**a.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept **VSOURCE**a.

Refer to wcsbth() note 5.

WCSHDR_DATEREF

```
#define WCSHDR_DATEREF 0x00004000
```

WCSHDR_LONGKEY

```
#define WCSHDR_LONGKEY 0x00008000
```

Bit mask for wcspih() and wcsbth() - accept long forms of the alternate binary table and pixel list WCS keywords.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept long forms of the alternate binary table and pixel list WCS keywords.

Refer to wcsbth() note 5.

WCSHDR_CNAMn

```
#define WCSHDR_CNAMn 0x00010000
```

Bit mask for wcspih() and wcsbth() - accept i**CNAM**n, **TCNAM**n, i**CRDE**n, **TCRDE**n, i**CSYE**n, **TCSYE**n.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept i**CNAM**n, **TCNAM**n, i**CRDE**n, **TCRDE**n, i**CSYE**n, **TCSYE**n.

Refer to wcsbth() note 5.

WCSHDR_AUXIMG

```
#define WCSHDR_AUXIMG 0x00020000
```

Bit mask for wcspih() and wcsbth() - allow the image-header form of an auxiliary WCS keyword to provide a default value for all images.

Bit mask for the *relax* argument of wcspih() and wcsbth() - allow the image-header form of an auxiliary WCS keyword with representation-wide scope to provide a default value for all images.

Refer to wcsbth() note 5.

WCSHDR_ALLIMG

```
#define WCSHDR_ALLIMG 0x00040000
```

Bit mask for wcspih() and wcsbth() - allow the image-header form of *all* image header WCS keywords to provide a default value for all images.

Bit mask for the *relax* argument of wcspih() and wcsbth() - allow the image-header form of *all* image header WCS keywords to provide a default value for all image arrays in a binary table (n.b. not pixel list).

Refer to wcsbth() note 5.

WCSHDR_IMGHEAD

```
#define WCSHDR_IMGHEAD 0x00100000
```

Bit mask for wcsbth() - restrict to image header keywords only.

Bit mask for the *keysel* argument of wcsbth() - restrict keyword types considered to image header keywords only.

WCSHDR_BIMGARR

```
#define WCSHDR_BIMGARR 0x00200000
```

Bit mask for wcsbth() - restrict to binary table image array keywords only.

Bit mask for the *keysel* argument of wcsbth() - restrict keyword types considered to binary table image array keywords only.

WCSHDR_PIXLIST

```
#define WCSHDR_PIXLIST 0x00400000
```

Bit mask for wcsbth() - restrict to pixel list keywords only.

Bit mask for the *keysel* argument of wcsbth() - restrict keyword types considered to pixel list keywords only.

WCSHDO_none

```
#define WCSHDO_none 0x00000
```

Bit mask for wcshdo() - don't write any extensions.

Bit mask for the *relax* argument of wcshdo() - don't write any extensions.

Refer to the notes for wcshdo().

WCSHDO_all

```
#define WCSHDO_all 0x000FF
```

Bit mask for wcshdo() - write all extensions.

Bit mask for the *relax* argument of wcshdo() - write all extensions.

Refer to the notes for wcshdo().

WCSHDO_safe

```
#define WCSHDO_safe 0x0000F
```

Bit mask for wcshdo() - write safe extensions only.

Bit mask for the *relax* argument of wcshdo() - write only extensions that are considered safe.

Refer to the notes for wcshdo().

WCSHDO_DOBSn

```
#define WCSHDO_DOBSn 0x00001
```

Bit mask for wcshdo() - write **DOBS**n.

Bit mask for the *relax* argument of wcshdo() - write **DOBS**n, the column-specific analogue of DATE-OBS for use in binary tables and pixel lists.

Refer to the notes for wcshdo().

WCSHDO_TPCn_ka

```
#define WCSHDO_TPCn_ka 0x00002
```

Bit mask for wcshdo() - write **TPC**n_ka.

Bit mask for the *relax* argument of wcshdo() - write **TPC**n_ka if less than eight characters instead of **TP**n_ka.

Refer to the notes for wcshdo().

WCSHDO_PVn_ma

```
#define WCSHDO_PVn_ma 0x00004
```

Bit mask for wcshdo() - write i**PV**n_ma, **TPV**n_ma, i**PS**n_ma, **TPS**n_ma.

Bit mask for the *relax* argument of wcshdo() - write i**PV**n_ma, **TPV**n_ma, i**PS**n_ma, **TPS**n_ma, if less than eight characters instead of i**V**n_ma, **TV**n_ma, i**S**n_ma, **TS**n_ma.

Refer to the notes for wcshdo().

WCSHDO_CRPXna

```
#define WCSHDO_CRPXna 0x00008
```

Bit mask for wcshdo() - write j**CRPX**na, **TCRPX**na, i**CDLT**na, **TCDLT**na, i**CUNI**na, **TCUNI**na, i**CTYP**na, **TCTYP**na, i**CRVL**na, **TCRVL**na.

Bit mask for the *relax* argument of wcshdo() - write j**CRPX**na, **TCRPX**na, i**CDLT**na, **TCDLT**na, i**CUNI**na, **TCUNI**na, i**CTYP**na, **TCTYP**na, i**CRVL**na, **TCRVL**na, if less than eight characters instead of j**CRP**na, **TCRP**na, i**CDE**na, **TCDE**na, i**CUN**na, **TCUN**na, i**CTY**na, **TCTY**na, i**CRV**na, **TCRV**na.

Refer to the notes for wcshdo().

WCSHDO_CNAMna

```
#define WCSHDO_CNAMna 0x00010
```

Bit mask for wcshdo() - write i**CNAM**na, **TCNAM**na, i**CRDE**na, **TCRDE**na, i**CSYE**na, **TCSYE**na.

Bit mask for the *relax* argument of wcshdo() - write i**CNAM**na, **TCNAM**na, i**CRDE**na, **TCRDE**na, i**CSYE**na, **TCSYE**na, if less than eight characters instead of i**CNA**na, **TCNA**na, i**CRD**na, **TCRD**na, i**CSY**na, **TCSY**na.

Refer to the notes for wcshdo().

WCSHDO_WCSNna

```
#define WCSHDO_WCSNna 0x00020
```

Bit mask for wcshdo() - write **WCSN**na instead of **TWCS**na

Bit mask for the *relax* argument of wcshdo() - write **WCSN**na instead of **TWCS**na.

Refer to the notes for wcshdo().

WCSHDO_P12

```
#define WCSHDO_P12 0x01000
```

WCSHDO_P13

```
#define WCSHDO_P13 0x02000
```

WCSHDO_P14

```

6.29.3 Enumeration Type Documentation

wcshdr_errmsg_enum

```
enum wcshdr_errmsg_enum
```

Enumerator

WCSHDRERR_SUCCESS	
WCSHDRERR_NULL_POINTER	
WCSHDRERR_MEMORY	
WCSHDRERR_BAD_COLUMN	
WCSHDRERR_PARSER	
WCSHDRERR_BAD_TABULAR_PARAMS	

6.29.4 Function Documentation

wcspih()

```
int wcspih (
              char * header,
              int nkeyrec,
              int relax,
              int ctrl,
              int * nreject,
              int * nwcs,
              struct wcsprm ** wcs )
```

FITS WCS parser routine for image headers.

wcspih() is a high-level FITS WCS routine that parses an image header, either that of a primary HDU or of an image extension. All WCS keywords defined in Papers I, II, III, IV, and VII are recognized, and also those used by the AIPS convention and certain other keywords that existed in early drafts of the WCS papers as explained in wcsbth() note 5. **wcspih**() also handles keywords associated with non-standard distortion functions described in the prologue of dis.h.

Given a character array containing a FITS image header, **wcspih**() identifies and reads all WCS keywords for the primary coordinate representation and up to 26 alternate representations. It returns this information as an array of wcsprm structs.

wcspih() invokes wcstab() on each of the wcsprm structs that it returns.

Use wcsbth() in preference to **wcspih**() for FITS headers of unknown type; wcsbth() can parse image headers as well as binary table and pixel list headers, although it cannot handle keywords relating to distortion functions, which may only exist in an image header (primary or extension).

Parameters

in,out	*header*	Character array containing the (entire) FITS image header from which to identify and construct the coordinate representations, for example, as might be obtained conveniently via the CFITSIO routine *fits_hdr2str()*. Each header "keyrecord" (formerly "card image") consists of exactly 80 7-bit ASCII printing characters in the range 0x20 to 0x7e (which excludes NUL, BS, TAB, LF, FF and CR) especially noting that the keyrecords are NOT null-terminated. For negative values of ctrl (see below), header[] is modified so that WCS keyrecords processed by **wcspih**() are removed from it.
in	*nkeyrec*	Number of keyrecords in header[].
in	*relax*	Degree of permissiveness: • 0: Recognize only FITS keywords defined by the published WCS standard. • WCSHDR_all: Admit all recognized informal extensions of the WCS standard. Fine-grained control of the degree of permissiveness is also possible as explained in wcsbth() note 5.

Parameters

in	*ctrl*	Error reporting and other control options for invalid WCS and other header keyrecords: • 0: Do not report any rejected header keyrecords. • 1: Produce a one-line message stating the number of WCS keyrecords rejected (nreject). • 2: Report each rejected keyrecord and the reason why it was rejected. • 3: As above, but also report all non-WCS keyrecords that were discarded, and the number of coordinate representations (nwcs) found. • 4: As above, but also report the accepted WCS keyrecords, with a summary of the number accepted as well as rejected. The report is written to stderr by default, or the stream set by wcsprintf_set(). For ctrl $<$ 0, WCS keyrecords processed by **wcspih**() are removed from header[]: • -1: Remove only valid WCS keyrecords whose values were successfully extracted, nothing is reported. • -2: As above, but also remove WCS keyrecords that were rejected, reporting each one and the reason that it was rejected. • -3: As above, and also report the number of coordinate representations (nwcs) found. • -11: Same as -1 but preserving global WCS-related keywords such as '{**DATE**,**MJD**}−{**OBS**,**BEG**,**AVG**,**END**}' and the other basic time-related keywords, and '**OBSGEO−**{**X**,**Y**,**Z**,**L**,**B**,**H**}'. If any keyrecords are removed from header[] it will be null-terminated (NUL not being a legal FITS header character), otherwise it will contain its original complement of nkeyrec keyrecords and possibly not be null-terminated.
out	*nreject*	Number of WCS keywords rejected for syntax errors, illegal values, etc. Keywords not recognized as WCS keywords are simply ignored. Refer also to wcsbth() note 5.
out	*nwcs*	Number of coordinate representations found.
out	*wcs*	Pointer to an array of wcsprm structs containing up to 27 coordinate representations. Memory for the array is allocated by **wcspih**() which also invokes wcsini() for each struct to allocate memory for internal arrays and initialize their members to default values. Refer also to wcsbth() note 8. Note that wcsset() is not invoked on these structs. This allocated memory must be freed by the user, first by invoking wcsfree() for each struct, and then by freeing the array itself. A routine, wcsvfree(), is provided to do this (see below).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 4: Fatal error returned by Flex parser.

Notes:

1. Refer to wcsbth() notes 1, 2, 3, 5, 7, and 8.

wcsbth()

```
int wcsbth (
              char * header,
              int nkeyrec,
              int relax,
              int ctrl,
              int keysel,
              int * colsel,
              int * nreject,
              int * nwcs,
              struct wcsprm ** wcs )
```

FITS WCS parser routine for binary table and image headers.

wcsbth() is a high-level FITS WCS routine that parses a binary table header. It handles image array and pixel list WCS keywords which may be present together in one header.

As an extension of the FITS WCS standard, **wcsbth**() also recognizes image header keywords in a binary table header. These may be used to provide default values via an inheritance mechanism discussed in note 5 (c.↩f. WCSHDR_AUXIMG and WCSHDR_ALLIMG), or may instead result in wcsprm structs that are not associated with any particular column. Thus **wcsbth**() can handle primary image and image extension headers in addition to binary table headers (it ignores **NAXIS** and does not rely on the presence of the **TFIELDS** keyword).

All WCS keywords defined in Papers I, II, III, and VII are recognized, and also those used by the AIPS convention and certain other keywords that existed in early drafts of the WCS papers as explained in note 5 below.

wcsbth() sets the colnum or colax[] members of the wcsprm structs that it returns with the column number of an image array or the column numbers associated with each pixel coordinate element in a pixel list. wcsprm structs that are not associated with any particular column, as may be derived from image header keywords, have colnum == 0.

Note 6 below discusses the number of wcsprm structs returned by **wcsbth**(), and the circumstances in which image header keywords cause a struct to be created. See also note 9 concerning the number of separate images that may be stored in a pixel list.

The API to **wcsbth**() is similar to that of wcspih() except for the addition of extra arguments that may be used to restrict its operation. Like wcspih(), **wcsbth**() invokes wcstab() on each of the wcsprm structs that it returns.

Parameters

in,out	*header*	Character array containing the (entire) FITS binary table, primary image, or image extension header from which to identify and construct the coordinate representations, for example, as might be obtained conveniently via the CFITSIO routine *fits_hdr2str()*. Each header "keyrecord" (formerly "card image") consists of exactly 80 7-bit ASCII printing characters in the range 0x20 to 0x7e (which excludes NUL, BS, TAB, LF, FF and CR) especially noting that the keyrecords are NOT null-terminated. For negative values of ctrl (see below), header[] is modified so that WCS keyrecords processed by **wcsbth**() are removed from it.
in	*nkeyrec*	Number of keyrecords in header[].
in	*relax*	Degree of permissiveness: • 0: Recognize only FITS keywords defined by the published WCS standard. • WCSHDR_all: Admit all recognized informal extensions of the WCS standard. Fine-grained control of the degree of permissiveness is also possible, as explained in note 5 below.

Parameters

in	*ctrl*	Error reporting and other control options for invalid WCS and other header keyrecords: • 0: Do not report any rejected header keyrecords. • 1: Produce a one-line message stating the number of WCS keyrecords rejected (nreject). • 2: Report each rejected keyrecord and the reason why it was rejected. • 3: As above, but also report all non-WCS keyrecords that were discarded, and the number of coordinate representations (nwcs) found. • 4: As above, but also report the accepted WCS keyrecords, with a summary of the number accepted as well as rejected. The report is written to stderr by default, or the stream set by wcsprintf_set(). For ctrl $<$ 0, WCS keyrecords processed by **wcsbth**() are removed from header[]: • -1: Remove only valid WCS keyrecords whose values were successfully extracted, nothing is reported. • -2: Also remove WCS keyrecords that were rejected, reporting each one and the reason that it was rejected. • -3: As above, and also report the number of coordinate representations (nwcs) found. • -11: Same as -1 but preserving global WCS-related keywords such as '{**DATE**,**MJD**}-{**OBS**,**BEG**,**AVG**,**END**}' and the other basic time-related keywords, and '**OBSGEO-**{**X**,**Y**,**Z**,**L**,**B**,**H**}'. If any keyrecords are removed from header[] it will be null-terminated (NUL not being a legal FITS header character), otherwise it will contain its original complement of nkeyrec keyrecords and possibly not be null-terminated.
in	*keysel*	Vector of flag bits that may be used to restrict the keyword types considered: • WCSHDR_IMGHEAD: Image header keywords. • WCSHDR_BIMGARR: Binary table image array. • WCSHDR_PIXLIST: Pixel list keywords. If zero, there is no restriction. Keywords such as **EQUI**na or **RFRQ**na that are common to binary table image arrays and pixel lists (including **WCSN**na and **TWCS**na, as explained in note 4 below) are selected by both WCSHDR_BIMGARR and WCSHDR_PIXLIST. Thus if inheritance via WCSHDR_ALLIMG is enabled as discussed in note 5 and one of these shared keywords is present, then WCSHDR_IMGHEAD and WCSHDR_PIXLIST alone may be sufficient to cause the construction of coordinate descriptions for binary table image arrays.

Parameters

in	*colsel*	Pointer to an array of table column numbers used to restrict the keywords considered by **wcsbth**(). A null pointer may be specified to indicate that there is no restriction. Otherwise, the magnitude of cols[0] specifies the length of the array: • cols[0] $>$ 0: the columns are included, • cols[0] $<$ 0: the columns are excluded. For the pixel list keywords **TP**n_ka and **TC**n_ka (and **TPC**n_ka and **TCD**n_ka if WCSHDR_LONGKEY is enabled), it is an error for one column to be selected but not the other. This is unlike the situation with invalid keyrecords, which are simply rejected, because the error is not intrinsic to the header itself but arises in the way that it is processed.
out	*nreject*	Number of WCS keywords rejected for syntax errors, illegal values, etc. Keywords not recognized as WCS keywords are simply ignored, refer also to note 5 below.
out	*nwcs*	Number of coordinate representations found.
out	*wcs*	Pointer to an array of wcsprm structs containing up to 27027 coordinate representations, refer to note 6 below. Memory for the array is allocated by **wcsbth**() which also invokes wcsini() for each struct to allocate memory for internal arrays and initialize their members to default values. Refer also to note 8 below. Note that wcsset() is not invoked on these structs. This allocated memory must be freed by the user, first by invoking wcsfree() for each struct, and then by freeing the array itself. A routine, wcsvfree(), is provided to do this (see below).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid column selection.
- 4: Fatal error returned by Flex parser.

Notes:

1. wcspih() determines the number of coordinate axes independently for each alternate coordinate representation (denoted by the "a" value in keywords like **CTYPE**ia) from the higher of

   a **NAXIS**,

   b **WCSAXES**a,

   c The highest axis number in any parameterized WCS keyword. The keyvalue, as well as the keyword, must be syntactically valid otherwise it will not be considered.

   If none of these keyword types is present, i.e. if the header only contains auxiliary WCS keywords for a particular coordinate representation, then no coordinate description is constructed for it.

   wcsbth() is similar except that it ignores the **NAXIS** keyword if given an image header to process.

   The number of axes, which is returned as a member of the wcsprm struct, may differ for different coordinate representations of the same image.

2. wcspih() and **wcsbth**() enforce correct FITS "keyword = value" syntax with regard to "= " occurring in columns 9 and 10.

   However, they do recognize free-format character (NOST 100-2.0, Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values (Sect. 5.2.4) for all keywords.

3. Where **CROTA**n, **CD**i_ja, and **PC**i_ja occur together in one header wcspih() and **wcsbth**() treat them as described in the prologue to wcs.h.

4. WCS Paper I mistakenly defined the pixel list form of **WCSNAME**a as **TWCS**na instead of **WCSN**na; the **'T'** is meant to substitute for the axis number in the binary table form of the keyword - note that keywords defined in WCS Papers II, III, and VII that are not parameterized by axis number have identical forms for binary tables and pixel lists. Consequently **wcsbth**() always treats **WCSN**na and **TWCS**na as equivalent.

5. wcspih() and **wcsbth**() interpret the *relax* argument as a vector of flag bits to provide fine-grained control over what non-standard WCS keywords to accept. The flag bits are subject to change in future and should be set by using the preprocessor macros (see below) for the purpose.

   - WCSHDR_none: Don't accept any extensions (not even those in the errata). Treat non-conformant keywords in the same way as non-WCS keywords in the header, i.e. simply ignore them.
   - WCSHDR_all: Accept all extensions recognized by the parser.
   - WCSHDR_reject: Reject non-standard keyrecords (that are not otherwise explicitly accepted by one of the flags below). A message will optionally be printed on stderr by default, or the stream set by wcsprintf_set(), as determined by the ctrl argument, and nreject will be incremented.

     This flag may be used to signal the presence of non-standard keywords, otherwise they are simply passed over as though they did not exist in the header. It is mainly intended for testing conformance of a FITS header to the WCS standard.

     Keyrecords may be non-standard in several ways:

     – The keyword may be syntactically valid but with keyvalue of incorrect type or invalid syntax, or the keycomment may be malformed.
     – The keyword may strongly resemble a WCS keyword but not, in fact, be one because it does not conform to the standard. For example, "CRPIX01" looks like a **CRPIX**ja keyword, but in fact the leading zero on the axis number violates the basic FITS standard. Likewise, "LONPOLE2" is not a valid **LONPOLE**a keyword in the WCS standard, and indeed there is nothing the parser can sensibly do with it.
     – Use of the keyword may be deprecated by the standard. Such will be rejected if not explicitly accepted via one of the flags below.
   - WCSHDR_strict: As for WCSHDR_reject, but also reject AIPS-convention keywords and all other deprecated usage that is not explicitly accepted.
   - WCSHDR_CROTAia: Accept **CROTA**ia (wcspih()), i**CROT**na (**wcsbth**()), **TCROT**na (**wcsbth**()).
   - WCSHDR_VELREFa: Accept **VELREF**a. wcspih() always recognizes the AIPS-convention keywords, **CROTA**n, **EPOCH**, and **VELREF** for the primary representation (a = ' ') but alternates are non-standard. **wcsbth**() accepts **EPOCH**a and **VELREF**a only if WCSHDR_AUXIMG is also enabled.
   - WCSHDR_CD00i00j: Accept **CD00**i**00**j (wcspih()).
   - WCSHDR_PC00i00j: Accept **PC00**i**00**j (wcspih()).
   - WCSHDR_PROJPn: Accept **PROJP**n (wcspih()). These appeared in early drafts of WCS Paper I+II (before they were split) and are equivalent to **CD**i_ja, **PC**i_ja, and **PV**i_ma for the primary representation (a = ' '). **PROJP**n is equivalent to **PV**i_ma with $m = n \leq 9$, and is associated exclusively with the latitude axis.
   - WCSHDR_CD0i_0ja: Accept CD0i_0ja (wcspih()).
   - WCSHDR_PC0i_0ja: Accept PC0i_0ja (wcspih()).
   - WCSHDR_PV0i_0ma: Accept PV0i_0ja (wcspih()).
   - WCSHDR_PS0i_0ma: Accept PS0i_0ja (wcspih()). Allow the numerical index to have a leading zero in doubly- parameterized keywords, for example, PC01_01. WCS Paper I (Sects 2.1.2 & 2.1.4) explicitly disallows leading zeroes. The FITS 3.0 standard document (Sect. 4.1.2.1) states that the index in singly-parameterized keywords (e.g. **CTYPE**ia) "shall not have leading zeroes", and later in Sect. 8.1 that "leading zeroes must not be used" on **PV**i_ma and **PS**i_ma. However, by an oversight, it is silent on **PC**i_ja and **CD**i_ja.

- WCSHDR_DOBSn (**wcsbth**() only): Allow **DOBS**n, the column-specific analogue of **DATE-OBS**. By an oversight this was never formally defined in the standard.
- WCSHDR_OBSGLBHn (**wcsbth**() only): Allow **OBSGL**n, **OBSGB**n, and **OBSGH**n, the column-specific analogues of **OBSGEO-L**, **OBSGEO-B**, and **OBSGEO-H**. By an oversight these were never formally defined in the standard.
- WCSHDR_RADECSYS: Accept **RADECSYS**. This appeared in early drafts of WCS Paper I+II and was subsequently replaced by **RADESYS**a.

  wcsbth() accepts **RADECSYS** only if WCSHDR_AUXIMG is also enabled.
- WCSHDR_EPOCHa: Accept **EPOCH**a.
- WCSHDR_VSOURCE: Accept **VSOURCE**a or **VSOU**na (**wcsbth**()). This appeared in early drafts of WCS Paper III and was subsequently dropped in favour of **ZSOURCE**a and **ZSOU**na.

  wcsbth() accepts **VSOURCE**a only if WCSHDR_AUXIMG is also enabled.
- #WCSHDR_<TT>**DATEREF**: Accept DATE-REF, MJD-REF, MJD-REFI, MJD-REFF, **JDREF**, JD-↩ REFI, and JD-REFF as synonyms for the standard keywords, **DATEREF**, **MJDREF**, **MJDREFI**, **MJDREFF**, **JDREF**, **JDREFI**, and **JDREFF**. The latter buck the pattern set by the other date keywords ({DATE,**MJD**}-{**OBS,BEG,AVG,**END}), thereby increasing the potential for confusion and error.
- WCSHDR_LONGKEY (**wcsbth**() only): Accept long forms of the alternate binary table and pixel list WCS keywords, i.e. with "a" non- blank. Specifically

j**CRPX**na	**TCRPX**na	↩ :	j**CRPX**n	j**CRP**na	**TCRPX**n	**TCRP**na	**CRPIX**ja
	TPCn_ka	↩ :		ij**PC**na		**TP**n_ka	**PC**i_ja
	TCDn_ka	↩ :		ij**CD**na		**TC**n_ka	**CD**i_ja
i**CDLT**na	**TCDLT**na	↩ :	i**CDLT**n	i**CDE**na	**TCDLT**n	**TCDE**na	**CDELT**ia
i**CUNI**na	**TCUNI**na	↩ :	i**CUNI**n	i**CUN**na	**TCUNI**n	**TCUN**na	**CUNIT**ia
i**CTYP**na	**TCTYP**na	↩ :	i**CTYP**n	i**CTY**na	**TCTYP**n	**TCTY**na	**CTYPE**ia
i**CRVL**na	**TCRVL**na	↩ :	i**CRVL**n	i**CRV**na	**TCRVL**n	**TCRV**na	**CRVAL**ia
i**PV**n_ma	**TPV**n_ma	↩ :		i**V**n_ma		**TV**n_ma	**PV**i_ma
i**PS**n_ma	**TPS**n_ma	↩ :		i**S**n_ma		**TS**n_ma	**PS**i_ma

where the primary and standard alternate forms together with the image-header equivalent are shown rightwards of the colon.

The long form of these keywords could be described as quasi- standard. **TPC**n_ka, i**PV**n_ma, and **TPV**n_ma appeared by mistake in the examples in WCS Paper II and subsequently these and also **TCD**n_ka, i**PS**n_ma and **TPS**n_ma were legitimized by the errata to the WCS papers.

Strictly speaking, the other long forms are non-standard and in fact have never appeared in any draft of the WCS papers nor in the errata. However, as natural extensions of the primary form they are unlikely to be written with any other intention. Thus it should be safe to accept them provided, of course, that the resulting keyword does not exceed the 8-character limit.

If WCSHDR_CNAMn is enabled then also accept

i**CNAM**na	**TCNAM**na	↩ :	--	i**CNA**na	--	**TCNA**na	**CNAME**ia

i**CRDE**na	**TCRDE**na	↩ :	--	i**CRD**na	--	**TCRD**na	**CRDER**ia
i**CSYE**na	**TCSYE**na	↩ :	--	i**CSY**na	--	**TCSY**na	**CSYER**ia
TCZPHna	**TCZPH**na	↩ :	--	**TCZP**na	--	**TCZP**na	CZPHSia
i**CPER**na	**TCPER**na	↩ :	--	i**CPR**na	--	**TCPR**na	CPERIia

Note that **CNAME**ia, **CRDER**ia, **CSYER**ia, CZPHSia, CPERIia, and their variants are not used by WCSLIB but are stored in the wcsprm struct as auxiliary information.

- WCSHDR_CNAMn (**wcsbth**() only): Accept i**CNAM**n, i**CRDE**n, i**CSYE**n, **TCZPH**n, i**CPER**n, **TCNAM**n, **TCRDE**n, **TCSYE**n, **TCZPH**n, and **TCPER**n, i.e. with "a" blank. While non-standard, these are the obvious analogues of i**CTYP**n, **TCTYP**n, etc.
- WCSHDR_AUXIMG (**wcsbth**() only): Allow the image-header form of an auxiliary WCS keyword with representation-wide scope to provide a default value for all images. This default may be overridden by the column-specific form of the keyword.

  For example, a keyword like **EQUINOX**a would apply to all image arrays in a binary table, or all pixel list columns with alternate representation "a" unless overridden by **EQUI**na.

  Specifically the keywords are:

LONPOLEa	for **LONP**na	
LATPOLEa	for **LATP**na	
VELREF		... (No column-specific form.)
VELREFa		... Only if WCSHDR_VELREFa is set.

whose keyvalues are actually used by WCSLIB, and also keywords providing auxiliary information that is simply stored in the wcsprm struct:

WCSNAMEa	for **WCSN**na	... Or **TWCS**na (see below).
DATE-OBS	for **DOBS**n	
MJD-OBS	for **MJDOB**n	
RADESYSa	for **RADE**na	
RADECSYS	for **RADE**na	... Only if WCSHDR_RADECSYS is set.
EPOCH		... (No column-specific form.)
EPOCHa		... Only if WCSHDR_EPOCHa is set.
EQUINOXa	for **EQUI**na	

where the image-header keywords on the left provide default values for the column specific keywords on the right.

Note that, according to Sect. 8.1 of WCS Paper III, and Sect. 5.2 of WCS Paper VII, the following are always inherited:

RESTFREQ	for **RFRQ**na
RESTFRQa	for **RFRQ**na
RESTWAVa	for **RWAV**na

being those actually used by WCSLIB, together with the following auxiliary keywords, many of which do not have binary table equivalents

and therefore can only be inherited:

TIMESYS		
TREFPOS	for **MJDA**n	
TREFDIR	for **MJDA**n	
PLEPHEM		
TIMEUNIT		
DATEREF		
MJDREF		
MJDREFI		
MJDREFF		
JDREF		
JDREFI		
JDREFF		
TIMEOFFS		
DATE-BEG		
DATE-AVG	for **DAVG**n	
DATE-END		
MJD-BEG		
MJD-AVG	for **MJDA**n	
MJD-END		
JEPOCH		
BEPOCH		
TSTART		
TSTOP		
XPOSURE		
TELAPSE		
TIMSYER		
TIMRDER		
TIMEDEL		
TIMEPIXR		
OBSGEO-X	for **OBSGX**n	
OBSGEO-Y	for **OBSGY**n	
OBSGEO-Z	for **OBSGZ**n	
OBSGEO-L	for **OBSGL**n	
OBSGEO-B	for **OBSGB**n	
OBSGEO-H	for **OBSGH**n	
OBSORBIT		
SPECSYSa	for **SPEC**na	
SSYSOBSa	for **SOBS**na	
VELOSYSa	for **VSYS**na	
VSOURCEa	for **VSOU**na	... Only if WCSHDR_VSOURCE is set.
ZSOURCEa	for **ZSOU**na	
SSYSSRCa	for **SSRC**na	
VELANGLa	for **VANG**na	

Global image-header keywords, such as **MJD-OBS**, apply to all alternate representations, and would therefore provide a default value for all images in the header.

This auxiliary inheritance mechanism applies to binary table image arrays and pixel lists alike. Most of these keywords have no default value, the exceptions being **LONPOLE**a and **LATPOLE**a, and also **RADESYS**a and **EQUINOX**a which provide defaults for each other. Thus one potential

difficulty in using WCSHDR_AUXIMG is that of erroneously inheriting one of these four keywords.

Also, beware of potential inconsistencies that may arise where, for example, **DATE-OBS** is inherited, but **MJD-OBS** is overridden by **MJDOB**n and specifies a different time. Pairs in this category are:

```
    DATE-OBS/DOBSn       versus       MJD-OBS/MJDOBn
    DATE-AVG/DAVGn       versus       MJD-AVG/MJDAn
    RESTFRQa/RFRQna      versus      RESTWAVa/RWAVna
OBSGEO-[XYZ]/OBSG[XYZ]n  versus  OBSGEO-[LBH]/OBSG[LBH]n
```

The wcsfixi() routines datfix() and obsfix() are provided to check the consistency of these and other such pairs of keywords.

Unlike WCSHDR_ALLIMG, the existence of one (or all) of these auxiliary WCS image header keywords will not by itself cause a wcsprm struct to be created for alternate representation "a". This is because they do not provide sufficient information to create a non-trivial coordinate representation when used in conjunction with the default values of those keywords that are parameterized by axis number, such as **CTYPE**ia.

- WCSHDR_ALLIMG (**wcsbth**() only): Allow the image-header form of *all* image header WCS keywords to provide a default value for all image arrays in a binary table (n.b. not pixel list). This default may be overridden by the column-specific form of the keyword.

  For example, a keyword like **CRPIX**ja would apply to all image arrays in a binary table with alternate representation "a" unless overridden by j**CRP**na.

  Specifically the keywords are those listed above for WCSHDR_AUXIMG plus

WCSAXESa	for **WCAX**na

which defines the coordinate dimensionality, and the following keywords that are parameterized by axis number:

CRPIXja	for j**CRP**na	
PCi_ja	for ij**PC**na	
CDi_ja	for ij**CD**na	
CDELTia	for i**CDE**na	
CROTAi	for i**CROT**n	
CROTAia		... Only if WCSHDR_CROTAia is set.
CUNITia	for i**CUN**na	
CTYPEia	for i**CTY**na	
CRVALia	for i**CRV**na	
PVi_ma	for i**V**n_ma	
PSi_ma	for i**S**n_ma	
CNAMEia	for i**CNA**na	
CRDERia	for i**CRD**na	
CSYERia	for i**CSY**na	
CZPHSia	for **TCZP**na	
CPERIia	for i**CPR**na	

where the image-header keywords on the left provide default values for the column specific keywords on the right.

This full inheritance mechanism only applies to binary table image arrays, not pixel lists, because in the latter case there is no well-defined association between coordinate axis number and column number (see note 9 below).

Note that **CNAME**ia, **CRDER**ia, **CSYER**ia, and their variants are not used by WCSLIB but are stored in the wcsprm struct as auxiliary information.

Note especially that at least one wcsprm struct will be returned for each "a" found in one of the image header keywords listed above:

- If the image header keywords for "a" ***are not*** inherited by a binary table, then the struct will not be associated with any particular table column number and it is up to the user to provide an association.
- If the image header keywords for "a" ***are*** inherited by a binary table image array, then those keywords are considered to be "exhausted" and do not result in a separate wcsprm struct.

For example, to accept **CD00i00j** and **PC00i00j** and reject all other extensions, use

```
relax = WCSHDR_reject | WCSHDR_CD00i00j | WCSHDR_PC00i00j;
```

The parser always treats **EPOCH** as subordinate to **EQUINOX**a if both are present, and **VSOURCE**a is always subordinate to **ZSOURCE**a.

Likewise, **VELREF** is subordinate to the formalism of WCS Paper III, see spcaips().

Neither wcspih() nor **wcsbth**() currently recognize the AIPS-convention keywords **ALTRPIX** or **ALTRVAL** which effectively define an alternative representation for a spectral axis.

6. Depending on what flags have been set in its *relax* argument, **wcsbth**() could return as many as 27027 wcsprm structs:

   - Up to 27 unattached representations derived from image header keywords.
   - Up to 27 structs for each of up to 999 columns containing an image arrays.
   - Up to 27 structs for a pixel list.

   Note that it is considered legitimate for a column to contain an image array and also form part of a pixel list, and in particular that **wcsbth**() does not check the **TFORM** keyword for a pixel list column to check that it is scalar.

   In practice, of course, a realistic binary table header is unlikely to contain more than a handful of images.

   In order for **wcsbth**() to create a wcsprm struct for a particular coordinate representation, at least one WCS keyword that defines an axis number must be present, either directly or by inheritance if WCSHDR_ALLIMG is set.

   When the image header keywords for an alternate representation are inherited by a binary table image array via WCSHDR_ALLIMG, those keywords are considered to be "exhausted" and do not result in a separate wcsprm struct. Otherwise they do.

7. Neither wcspih() nor **wcsbth**() check for duplicated keywords, in most cases they accept the last encountered.

8. wcspih() and **wcsbth**() use wcsnpv() and wcsnps() (refer to the prologue of wcs.h) to match the size of the pv[] and ps[] arrays in the wcsprm structs to the number in the header. Consequently there are no unused elements in the pv[] and ps[] arrays, indeed they will often be of zero length.

9. The FITS WCS standard for pixel lists assumes that a pixel list defines one and only one image, i.e. that each row of the binary table refers to just one event, e.g. the detection of a single photon or neutrino,

for which the device "pixel" coordinates are stored in separate scalar columns of the table.

In the absence of a standard for pixel lists - or even an informal description! - let alone a formal mechanism for identifying the columns containing pixel coordinates (as opposed to pixel values or metadata recorded at the time the photon or neutrino was detected), WCS Paper I discusses how the WCS keywords themselves may be used to identify them.

In practice, however, pixel lists have been used to store multiple images. Besides not specifying how to identify columns, the pixel list convention is also silent on the method to be used to associate table columns with image axes.

An additional shortcoming is the absence of a formal method for associating global binary-table WCS keywords, such as **WCSN**na or **MJDOB**n, with a pixel list image, whether one or several.

In light of these uncertainties, **wcsbth**() simply collects all WCS keywords for a particular pixel list coordinate representation (i.e. the "a" value in **TCTY**na) into one wcsprm struct. However, these alternates need not be associated with the same table columns and this allows a pixel list to contain up to 27 separate images. As usual, if one of these representations happened to contain more than two celestial axes, for example, then an error would result when wcsset() is invoked on it. In this case the "colsel" argument could be used to restrict the columns used to construct the representation so that it only contained one pair of celestial axes.

Global, binary-table WCS keywords are considered to apply to the pixel list image with matching alternate (e.g. the "a" value in **LONP**na or **EQUI**na), regardless of the table columns the image occupies. In other words, the column number is ignored (the "n" value in **LONP**na or **EQUI**na). This also applies for global, binary-table WCS keywords that have no alternates, such as **MJDOB**n and **OBSGX**n, which match all images in a pixel list. Take heed that this may lead to counterintuitive behaviour, especially where such a keyword references a column that does not store pixel coordinates, and moreso where the pixel list stores only a single image. In fact, as the column number, n, is ignored for such keywords, it would make no difference even if they referenced non-existent columns. Moreover, there is no requirement for consistency in the column numbers used for such keywords, even for **OBSGX**n, **OBSGY**n, and **OBSGZ**n which are meant to define the elements of a coordinate vector. Although it would surely be perverse to construct a pixel list like this, such a situation may still arise in practice where columns are deleted from a binary table.

The situation with global, binary-table WCS keywords becomes potentially even more confusing when image arrays and pixel list images coexist in one binary table. In that case, a keyword such as **MJDOB**n may legitimately appear multiple times with n referencing different image arrays. Which then is the one that applies to the pixel list images? In this implementation, it is the last instance that appears in the header, whether or not it is also associated with an image array.

wcstab()

```
int wcstab (
            struct wcsprm * wcs )
```

Tabular construction routine.

wcstab() assists in filling in the information in the wcsprm struct relating to coordinate lookup tables.

Tabular coordinates (`'TAB'`) present certain difficulties in that the main components of the lookup table - the multidimensional coordinate array plus an index vector for each dimension - are stored in a FITS binary table extension (BINTABLE). Information required to locate these arrays is stored in `PVi_ma` and `PSi_ma` keywords in the image header.

wcstab() parses the `PVi_ma` and `PSi_ma` keywords associated with each `'TAB'` axis and allocates memory in the wcsprm struct for the required number of tabprm structs. It sets as much of the tabprm struct as can be gleaned from the image header, and also sets up an array of wtbarr structs (described in the prologue of wtbarr.h) to assist in extracting the required arrays from the BINTABLE extension(s).

It is then up to the user to allocate memory for, and copy arrays from the BINTABLE extension(s) into the tabprm structs. A CFITSIO routine, fits_read_wcstab(), has been provided for this purpose, see getwcstab.h. wcsset() will automatically take control of this allocated memory, in particular causing it to be freed by wcsfree(); the user must not attempt to free it after wcsset() has been called.

Note that wcspih() and wcsbth() automatically invoke **wcstab**() on each of the wcsprm structs that they return.

Parameters

in,out	*wcs*	Coordinate transformation parameters (see below). **wcstab**() sets ntab, tab, nwtb and wtb, allocating memory for the tab and wtb arrays. This allocated memory will be freed automatically by wcsfree().

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid tabular parameters.

For returns $>$ 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcsidx()

```
int wcsidx (
              int nwcs,
              struct wcsprm ** wcs,
              int alts[27] )
```

Index alternate coordinate representations.

wcsidx() returns an array of 27 indices for the alternate coordinate representations in the array of wcsprm structs returned by wcspih(). For the array returned by wcsbth() it returns indices for the unattached (colnum == 0) representations derived from image header keywords - use wcsbdx() for those derived from binary table image arrays or pixel lists keywords.

Parameters

in	*nwcs*	Number of coordinate representations in the array.
in	*wcs*	Pointer to an array of wcsprm structs returned by wcspih() or wcsbth().

Parameters

out	*alts*	Index of each alternate coordinate representation in the array: alts[0] for the primary, alts[1] for 'A', etc., set to -1 if not present.
		For example, if there was no 'P' representation then
		`alts['P'-'A'+1] == -1;`
		
		Otherwise, the address of its wcsprm struct would be
		`wcs + alts['P'-'A'+1];`

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsbdx()

```
int wcsbdx (
            int nwcs,
            struct wcsprm ** wcs,
            int type,
            short alts[1000][28] )
```

Index alternate coordinate represention.

wcsbdx() returns an array of 999 x 27 indices for the alternate coordinate represention for binary table image arrays xor pixel lists in the array of wcsprm structs returned by wcsbth(). Use wcsidx() for the unattached representations derived from image header keywords.

Parameters

in	*nwcs*	Number of coordinate representations in the array.
in	*wcs*	Pointer to an array of wcsprm structs returned by wcsbth().
in	*type*	Select the type of coordinate representation: • 0: binary table image arrays, • 1: pixel lists.

out	*alts*	Index of each alternate coordinate represention in the array: alts[col][0] for the primary, alts[col][1] for 'A', to alts[col][26] for 'Z', where col is the 1-relative column number, and col == 0 is used for unattached image headers. Set to -1 if not present.
		alts[col][27] counts the number of coordinate representations of the chosen type for each column.
		For example, if there was no 'P' represention for column 13 then
		`alts[13]['P'-'A'+1] == -1;`
		
		Otherwise, the address of its wcsprm struct would be
		`wcs + alts[13]['P'-'A'+1];`

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsvfree()

```
int wcsvfree (
              int * nwcs,
              struct wcsprm ** wcs )
```

Free the array of wcsprm structs.

wcsvfree() frees the memory allocated by wcspih() or wcsbth() for the array of wcsprm structs, first invoking wcsfree() on each of the array members.

Parameters

in,out	*nwcs*	Number of coordinate representations found; set to 0 on return.
in,out	*wcs*	Pointer to the array of wcsprm structs; set to 0x0 on return.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcshdo()

```
int wcshdo (
              int ctrl,
              struct wcsprm * wcs,
              int * nkeyrec,
              char ** header )
```

Write out a wcsprm struct as a FITS header.

wcshdo() translates a wcsprm struct into a FITS header. If the colnum member of the struct is non-zero then a binary table image array header will be produced. Otherwise, if the colax[] member of the struct is set non-zero then a pixel list header will be produced. Otherwise, a primary image or image extension header will be produced.

If the struct was originally constructed from a header, e.g. by wcspih(), the output header will almost certainly differ in a number of respects:

- The output header only contains WCS-related keywords. In particular, it does not contain syntactically-required keywords such as **SIMPLE**, **NAXIS**, **BITPIX**, or **END**.
- Elements of the **PC**i_ja matrix will be written if and only if they differ from the unit matrix. Thus, if the matrix is unity then no elements will be written.

- The redundant keywords **MJDREF**, **JDREF**, **JDREFI**, **JDREFF**, all of which duplicate **MJDREFI** + **MJDREFF**, are never written. OBSGEO-[LBH] are not written if OBSGEO-[XYZ] are defined.
- Deprecated (e.g. **CROTA**n, **RESTFREQ**, **VELREF**, **RADECSYS**, **EPOCH**, **VSOURCE**a) or non-standard usage will be translated to standard (this is partially dependent on whether wcsfix() was applied).
- Additional keywords such as **WCSAXES**a, **CUNIT**ia, **LONPOLE**a and **LATPOLE**a may appear.
- Quantities will be converted to the units used internally, basically SI with the addition of degrees.
- Floating-point quantities may be given to a different decimal precision.
- The original keycomments will be lost, although **wcshdo**() tries hard to write meaningful comments.
- Keyword order will almost certainly be changed.

Keywords can be translated between the image array, binary table, and pixel lists forms by manipulating the colnum or colax[] members of the wcsprm struct.

Parameters

in	*ctrl*	Vector of flag bits that controls the degree of permissiveness in departing from the published WCS standard, and also controls the formatting of floating-point keyvalues. Set it to zero to get the default behaviour. Flag bits for the degree of permissiveness: • WCSHDO_none: Recognize only FITS keywords defined by the published WCS standard. • WCSHDO_all: Admit all recognized informal extensions of the WCS standard. Fine-grained control of the degree of permissiveness is also possible as explained in the notes below. As for controlling floating-point formatting, by default **wcshdo**() uses "%20.12G" for non-parameterized keywords such as **LONPOLE**a, and attempts to make the header more human-readable by using the same "f" format for all values of each of the following parameterized keywords: **CRPIX**ja, **PC**i_ja, and **CDELT**ia (n.b. excluding **CRVAL**ia). Each has the same field width and precision so that the decimal points line up. The precision, allowing for up to 15 significant digits, is chosen so that there are no excess trailing zeroes. A similar formatting scheme applies by default for distortion function parameters. However, where the values of, for example, **CDELT**ia differ by many orders of magnitude, the default formatting scheme may cause unacceptable loss of precision for the lower-valued keyvalues. Thus the default behaviour may be overridden: • WCSHDO_P12: Use "%20.12G" format for all floating- point keyvalues (12 significant digits). • WCSHDO_P13: Use "%21.13G" format for all floating- point keyvalues (13 significant digits). • WCSHDO_P14: Use "%22.14G" format for all floating- point keyvalues (14 significant digits). • WCSHDO_P15: Use "%23.15G" format for all floating- point keyvalues (15 significant digits). • WCSHDO_P16: Use "%24.16G" format for all floating- point keyvalues (16 significant digits). • WCSHDO_P17: Use "%25.17G" format for all floating- point keyvalues (17 significant digits). If more than one of the above flags are set, the highest number of significant digits prevails. In addition, there is an anciliary flag: • WCSHDO_EFMT: Use "E" format instead of the default "G" format above. Note that excess trailing zeroes are stripped off the fractional part with "G" (which never occurs with "E"). Note also that the higher-precision options eat into the keycomment area. In this regard, WCSHDO_P14 causes minimal disruption with "G" format, while WCSHDO_P13 is appropriate with "E".
in,out	*wcs*	Pointer to a wcsprm struct containing coordinate transformation parameters. Will be initialized if necessary.
out	*nkeyrec*	Number of FITS header keyrecords returned in the "header" array.
out	*header*	Pointer to an array of char holding the header. Storage for the array is allocated by **wcshdo**() in blocks of 2880 bytes (32 x 80-character keyrecords) and must be freed by the user to avoid memory leaks. See wcsdealloc(). Each keyrecord is 80 characters long and is ∗NOT∗ null-terminated, so the first keyrecord starts at (∗header)[0], the second at (∗header)[80], etc.

Returns

Status return value (associated with wcs_errmsg[]):

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

Notes:

1. **wcshdo**() interprets the *relax* argument as a vector of flag bits to provide fine-grained control over what non-standard WCS keywords to write. The flag bits are subject to change in future and should be set by using the preprocessor macros (see below) for the purpose.

   - WCSHDO_none: Don't use any extensions.
   - WCSHDO_all: Write all recognized extensions, equivalent to setting each flag bit.
   - WCSHDO_safe: Write all extensions that are considered to be safe and recommended.
   - WCSHDO_DOBSn: Write **DOBS**n, the column-specific analogue of **DATE-OBS** for use in binary tables and pixel lists. WCS Paper III introduced **DATE-AVG** and **DAVG**n but by an oversight **DOBS**n (the obvious analogy) was never formally defined by the standard. The alternative to using **DOBS**n is to write **DATE-OBS** which applies to the whole table. This usage is considered to be safe and is recommended.
   - WCSHDO_TPCn_ka: WCS Paper I defined
     - **TP**n_ka and **TC**n_ka for pixel lists

     but WCS Paper II uses **TPC**n_ka in one example and subsequently the errata for the WCS papers legitimized the use of
     - **TPC**n_ka and **TCD**n_ka for pixel lists

     provided that the keyword does not exceed eight characters. This usage is considered to be safe and is recommended because of the non-mnemonic terseness of the shorter forms.
   - WCSHDO_PVn_ma: WCS Paper I defined
     - i**V**n_ma and i**S**n_ma for bintables and
     - **TV**n_ma and **TS**n_ma for pixel lists

     but WCS Paper II uses i**PV**n_ma and **TPV**n_ma in the examples and subsequently the errata for the WCS papers legitimized the use of
     - i**PV**n_ma and i**PS**n_ma for bintables and
     - **TPV**n_ma and **TPS**n_ma for pixel lists

     provided that the keyword does not exceed eight characters. This usage is considered to be safe and is recommended because of the non-mnemonic terseness of the shorter forms.
   - WCSHDO_CRPXna: For historical reasons WCS Paper I defined
     - j**CRPX**n, i**CDLT**n, i**CUNI**n, i**CTYP**n, and i**CRVL**n for bintables and
     - **TCRPX**n, **TCDLT**n, **TCUNI**n, **TCTYP**n, and **TCRVL**n for pixel lists

     for use without an alternate version specifier. However, because of the eight-character keyword constraint, in order to accommodate column numbers greater than 99 WCS Paper I also defined

  - jCRPna, iCDEna, iCUNna, iCTYna and iCRVna for bintables and
  - TCRPna, TCDEna, TCUNna, TCTYna and TCRVna for pixel lists

  for use with an alternate version specifier (the "a"). Like the PC, CD, PV, and PS keywords there is an obvious tendency to confuse these two forms for column numbers up to 99. It is very unlikely that any parser would reject keywords in the first set with a non-blank alternate version specifier so this usage is considered to be safe and is recommended.

- WCSHDO_CNAMna: WCS Papers I and III defined
  - iCNAna, iCRDna, and iCSYna for bintables and
  - TCNAna, TCRDna, and TCSYna for pixel lists

  By analogy with the above, the long forms would be
  - iCNAMna, iCRDEna, and iCSYEna for bintables and
  - TCNAMna, TCRDEna, and TCSYEna for pixel lists

  Note that these keywords provide auxiliary information only, none of them are needed to compute world coordinates. This usage is potentially unsafe and is not recommended at this time.
- WCSHDO_WCSNna: In light of wcsbth() note 4, write WCSNna instead of TWCSna for pixel lists. While wcsbth() treats WCSNna and TWCSna as equivalent, other parsers may not. Consequently, this usage is potentially unsafe and is not recommended at this time.

6.29.5 Variable Documentation

wcshdr_errmsg

```
const char * wcshdr_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function. Use wcs_errmsg[] for status returns from **wcshdo**().

6.30 wcshdr.h

00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
```

```
00030 * Summary of the wcshdr routines
00031 * ------------------------------
00032 * Routines in this suite are aimed at extracting WCS information from a FITS
00033 * file.  The information is encoded via keywords defined in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 =
00038 =   "Representations of celestial coordinates in FITS",
00039 =   Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
00040 =
00041 =   "Representations of spectral coordinates in FITS",
00042 =   Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00043 =   2006, A&A, 446, 747 (WCS Paper III)
00044 =
00045 =   "Representations of distortions in FITS world coordinate systems",
00046 =   Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
00047 =   available from http://www.atnf.csiro.au/people/Mark.Calabretta
00048 =
00049 =   "Representations of time coordinates in FITS -
00050 =    Time and relative dimension in space",
00051 =   Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
00052 =   Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
00053 *
00054 * These routines provide the high-level interface between the FITS file and
00055 * the WCS coordinate transformation routines.
00056 *
00057 * Additionally, function wcshdo() is provided to write out the contents of a
00058 * wcsprm struct as a FITS header.
00059 *
00060 * Briefly, the anticipated sequence of operations is as follows:
00061 *
00062 *   - 1: Open the FITS file and read the image or binary table header, e.g.
00063 *        using CFITSIO routine fits_hdr2str().
00064 *
00065 *   - 2: Parse the header using wcspih() or wcsbth(); they will automatically
00066 *        interpret 'TAB' header keywords using wcstab().
00067 *
00068 *   - 3: Allocate memory for, and read 'TAB' arrays from the binary table
00069 *        extension, e.g. using CFITSIO routine fits_read_wcstab() - refer to
00070 *        the prologue of getwcstab.h.  wcsset() will automatically take
00071 *        control of this allocated memory, in particular causing it to be
00072 *        freed by wcsfree().
00073 *
00074 *   - 4: Translate non-standard WCS usage using wcsfix(), see wcsfix.h.
00075 *
00076 *   - 5: Initialize wcsprm struct(s) using wcsset() and calculate coordinates
00077 *        using wcsp2s() and/or wcss2p().  Refer to the prologue of wcs.h for a
00078 *        description of these and other high-level WCS coordinate
00079 *        transformation routines.
00080 *
00081 *   - 6: Clean up by freeing memory with wcsvfree().
00082 *
00083 * In detail:
00084 *
00085 * - wcspih() is a high-level FITS WCS routine that parses an image header.  It
00086 *   returns an array of up to 27 wcsprm structs on each of which it invokes
00087 *   wcstab().
00088 *
00089 * - wcsbth() is the analogue of wcspih() for use with binary tables; it
00090 *   handles image array and pixel list keywords.  As an extension of the FITS
00091 *   WCS standard, it also recognizes image header keywords which may be used
00092 *   to provide default values via an inheritance mechanism.
00093 *
00094 * - wcstab() assists in filling in members of the wcsprm struct associated
00095 *   with coordinate lookup tables ('TAB').  These are based on arrays stored
00096 *   in a FITS binary table extension (BINTABLE) that are located by PVi_ma
00097 *   keywords in the image header.
00098 *
00099 * - wcsidx() and wcsbdx() are utility routines that return the index for a
00100 *   specified alternate coordinate descriptor in the array of wcsprm structs
00101 *   returned by wcspih() or wcsbth().
00102 *
00103 * - wcsvfree() deallocates memory for an array of wcsprm structs, such as
00104 *   returned by wcspih() or wcsbth().
00105 *
00106 * - wcshdo() writes out a wcsprm struct as a FITS header.
00107 *
00108 *
00109 * wcspih() - FITS WCS parser routine for image headers
00110 * ---------------------------------------------------
00111 * wcspih() is a high-level FITS WCS routine that parses an image header,
00112 * either that of a primary HDU or of an image extension.  All WCS keywords
00113 * defined in Papers I, II, III, IV, and VII are recognized, and also those
00114 * used by the AIPS convention and certain other keywords that existed in early
00115 * drafts of the WCS papers as explained in wcsbth() note 5.  wcspih() also
00116 * handles keywords associated with non-standard distortion functions described
```

```
00117 * in the prologue of dis.h.
00118 *
00119 * Given a character array containing a FITS image header, wcspih() identifies
00120 * and reads all WCS keywords for the primary coordinate representation and up
00121 * to 26 alternate representations.  It returns this information as an array of
00122 * wcsprm structs.
00123 *
00124 * wcspih() invokes wcstab() on each of the wcsprm structs that it returns.
00125 *
00126 * Use wcsbth() in preference to wcspih() for FITS headers of unknown type;
00127 * wcsbth() can parse image headers as well as binary table and pixel list
00128 * headers, although it cannot handle keywords relating to distortion
00129 * functions, which may only exist in an image header (primary or extension).
00130 *
00131 * Given and returned:
00132 *   header    char[]    Character array containing the (entire) FITS image
00133 *                       header from which to identify and construct the
00134 *                       coordinate representations, for example, as might be
00135 *                       obtained conveniently via the CFITSIO routine
00136 *                       fits_hdr2str().
00137 *
00138 *                       Each header "keyrecord" (formerly "card image")
00139 *                       consists of exactly 80 7-bit ASCII printing characters
00140 *                       in the range 0x20 to 0x7e (which excludes NUL, BS,
00141 *                       TAB, LF, FF and CR) especially noting that the
00142 *                       keyrecords are NOT null-terminated.
00143 *
00144 *                       For negative values of ctrl (see below), header[] is
00145 *                       modified so that WCS keyrecords processed by wcspih()
00146 *                       are removed from it.
00147 *
00148 * Given:
00149 *   nkeyrec   int       Number of keyrecords in header[].
00150 *
00151 *   relax     int       Degree of permissiveness:
00152 *                         0: Recognize only FITS keywords defined by the
00153 *                            published WCS standard.
00154 *                       WCSHDR_all: Admit all recognized informal
00155 *                            extensions of the WCS standard.
00156 *                       Fine-grained control of the degree of permissiveness
00157 *                       is also possible as explained in wcsbth() note 5.
00158 *
00159 *   ctrl      int       Error reporting and other control options for invalid
00160 *                       WCS and other header keyrecords:
00161 *                           0: Do not report any rejected header keyrecords.
00162 *                           1: Produce a one-line message stating the number
00163 *                              of WCS keyrecords rejected (nreject).
00164 *                           2: Report each rejected keyrecord and the reason
00165 *                              why it was rejected.
00166 *                           3: As above, but also report all non-WCS
00167 *                              keyrecords that were discarded, and the number
00168 *                              of coordinate representations (nwcs) found.
00169 *                           4: As above, but also report the accepted WCS
00170 *                              keyrecords, with a summary of the number
00171 *                              accepted as well as rejected.
00172 *                       The report is written to stderr by default, or the
00173 *                       stream set by wcsprintf_set().
00174 *
00175 *                       For ctrl < 0, WCS keyrecords processed by wcspih()
00176 *                       are removed from header[]:
00177 *                          -1: Remove only valid WCS keyrecords whose values
00178 *                              were successfully extracted, nothing is
00179 *                              reported.
00180 *                          -2: As above, but also remove WCS keyrecords that
00181 *                              were rejected, reporting each one and the
00182 *                              reason that it was rejected.
00183 *                          -3: As above, and also report the number of
00184 *                              coordinate representations (nwcs) found.
00185 *                         -11: Same as -1 but preserving global WCS-related
00186 *                              keywords such as '{DATE,MJD}-{OBS,BEG,AVG,END}'
00187 *                              and the other basic time-related keywords, and
00188 *                              'OBSGEO-{X,Y,Z,L,B,H}'.
00189 *                       If any keyrecords are removed from header[] it will
00190 *                       be null-terminated (NUL not being a legal FITS header
00191 *                       character), otherwise it will contain its original
00192 *                       complement of nkeyrec keyrecords and possibly not be
00193 *                       null-terminated.
00194 *
00195 * Returned:
00196 *   nreject   int*      Number of WCS keywords rejected for syntax errors,
00197 *                       illegal values, etc.  Keywords not recognized as WCS
00198 *                       keywords are simply ignored.  Refer also to wcsbth()
00199 *                       note 5.
00200 *
00201 *   nwcs      int*      Number of coordinate representations found.
00202 *
00203 *   wcs       struct wcsprm**
```

```
00204 *                       Pointer to an array of wcsprm structs containing up to
00205 *                       27 coordinate representations.
00206 *
00207 *                       Memory for the array is allocated by wcspih() which
00208 *                       also invokes wcsini() for each struct to allocate
00209 *                       memory for internal arrays and initialize their
00210 *                       members to default values.  Refer also to wcsbth()
00211 *                       note 8.  Note that wcsset() is not invoked on these
00212 *                       structs.
00213 *
00214 *                       This allocated memory must be freed by the user, first
00215 *                       by invoking wcsfree() for each struct, and then by
00216 *                       freeing the array itself.  A routine, wcsvfree(), is
00217 *                       provided to do this (see below).
00218 *
00219 * Function return value:
00220 *             int       Status return value:
00221 *                         0: Success.
00222 *                         1: Null wcsprm pointer passed.
00223 *                         2: Memory allocation failed.
00224 *                         4: Fatal error returned by Flex parser.
00225 *
00226 * Notes:
00227 *   1: Refer to wcsbth() notes 1, 2, 3, 5, 7, and 8.
00228 *
00229 *
00230 * wcsbth() - FITS WCS parser routine for binary table and image headers
00231 * ---------------------------------------------------------------------
00232 * wcsbth() is a high-level FITS WCS routine that parses a binary table header.
00233 * It handles image array and pixel list WCS keywords which may be present
00234 * together in one header.
00235 *
00236 * As an extension of the FITS WCS standard, wcsbth() also recognizes image
00237 * header keywords in a binary table header.  These may be used to provide
00238 * default values via an inheritance mechanism discussed in note 5 (c.f.
00239 * WCSHDR_AUXIMG and WCSHDR_ALLIMG), or may instead result in wcsprm structs
00240 * that are not associated with any particular column.  Thus wcsbth() can
00241 * handle primary image and image extension headers in addition to binary table
00242 * headers (it ignores NAXIS and does not rely on the presence of the TFIELDS
00243 * keyword).
00244 *
00245 * All WCS keywords defined in Papers I, II, III, and VII are recognized, and
00246 * also those used by the AIPS convention and certain other keywords that
00247 * existed in early drafts of the WCS papers as explained in note 5 below.
00248 *
00249 * wcsbth() sets the colnum or colax[] members of the wcsprm structs that it
00250 * returns with the column number of an image array or the column numbers
00251 * associated with each pixel coordinate element in a pixel list.  wcsprm
00252 * structs that are not associated with any particular column, as may be
00253 * derived from image header keywords, have colnum == 0.
00254 *
00255 * Note 6 below discusses the number of wcsprm structs returned by wcsbth(),
00256 * and the circumstances in which image header keywords cause a struct to be
00257 * created.  See also note 9 concerning the number of separate images that may
00258 * be stored in a pixel list.
00259 *
00260 * The API to wcsbth() is similar to that of wcspih() except for the addition
00261 * of extra arguments that may be used to restrict its operation.  Like
00262 * wcspih(), wcsbth() invokes wcstab() on each of the wcsprm structs that it
00263 * returns.
00264 *
00265 * Given and returned:
00266 *   header    char[]    Character array containing the (entire) FITS binary
00267 *                       table, primary image, or image extension header from
00268 *                       which to identify and construct the coordinate
00269 *                       representations, for example, as might be obtained
00270 *                       conveniently via the CFITSIO routine fits_hdr2str().
00271 *
00272 *                       Each header "keyrecord" (formerly "card image")
00273 *                       consists of exactly 80 7-bit ASCII printing
00274 *                       characters in the range 0x20 to 0x7e (which excludes
00275 *                       NUL, BS, TAB, LF, FF and CR) especially noting that
00276 *                       the keyrecords are NOT null-terminated.
00277 *
00278 *                       For negative values of ctrl (see below), header[] is
00279 *                       modified so that WCS keyrecords processed by wcsbth()
00280 *                       are removed from it.
00281 *
00282 * Given:
00283 *   nkeyrec   int       Number of keyrecords in header[].
00284 *
00285 *   relax     int       Degree of permissiveness:
00286 *                         0: Recognize only FITS keywords defined by the
00287 *                            published WCS standard.
00288 *                       WCSHDR_all: Admit all recognized informal
00289 *                            extensions of the WCS standard.
00290 *                       Fine-grained control of the degree of permissiveness
```

```
00291 *                       is also possible, as explained in note 5 below.
00292 *
00293 *   ctrl      int       Error reporting and other control options for invalid
00294 *                       WCS and other header keyrecords:
00295 *                           0: Do not report any rejected header keyrecords.
00296 *                           1: Produce a one-line message stating the number
00297 *                              of WCS keyrecords rejected (nreject).
00298 *                           2: Report each rejected keyrecord and the reason
00299 *                              why it was rejected.
00300 *                           3: As above, but also report all non-WCS
00301 *                              keyrecords that were discarded, and the number
00302 *                              of coordinate representations (nwcs) found.
00303 *                           4: As above, but also report the accepted WCS
00304 *                              keyrecords, with a summary of the number
00305 *                              accepted as well as rejected.
00306 *                       The report is written to stderr by default, or the
00307 *                       stream set by wcsprintf_set().
00308 *
00309 *                       For ctrl < 0, WCS keyrecords processed by wcsbth()
00310 *                       are removed from header[]:
00311 *                          -1: Remove only valid WCS keyrecords whose values
00312 *                              were successfully extracted, nothing is
00313 *                              reported.
00314 *                          -2: Also remove WCS keyrecords that were rejected,
00315 *                              reporting each one and the reason that it was
00316 *                              rejected.
00317 *                          -3: As above, and also report the number of
00318 *                              coordinate representations (nwcs) found.
00319 *                         -11: Same as -1 but preserving global WCS-related
00320 *                              keywords such as '{DATE,MJD}-{OBS,BEG,AVG,END}'
00321 *                              and the other basic time-related keywords, and
00322 *                              'OBSGEO-{X,Y,Z,L,B,H}'.
00323 *                       If any keyrecords are removed from header[] it will
00324 *                       be null-terminated (NUL not being a legal FITS header
00325 *                       character), otherwise it will contain its original
00326 *                       complement of nkeyrec keyrecords and possibly not be
00327 *                       null-terminated.
00328 *
00329 *   keysel    int       Vector of flag bits that may be used to restrict the
00330 *                       keyword types considered:
00331 *                         WCSHDR_IMGHEAD: Image header keywords.
00332 *                         WCSHDR_BIMGARR: Binary table image array.
00333 *                         WCSHDR_PIXLIST: Pixel list keywords.
00334 *                       If zero, there is no restriction.
00335 *
00336 *                       Keywords such as EQUIna or RFRQna that are common to
00337 *                       binary table image arrays and pixel lists (including
00338 *                       WCSNna and TWCSna, as explained in note 4 below) are
00339 *                       selected by both WCSHDR_BIMGARR and WCSHDR_PIXLIST.
00340 *                       Thus if inheritance via WCSHDR_ALLIMG is enabled as
00341 *                       discussed in note 5 and one of these shared keywords
00342 *                       is present, then WCSHDR_IMGHEAD and WCSHDR_PIXLIST
00343 *                       alone may be sufficient to cause the construction of
00344 *                       coordinate descriptions for binary table image arrays.
00345 *
00346 *   colsel    int*      Pointer to an array of table column numbers used to
00347 *                       restrict the keywords considered by wcsbth().
00348 *
00349 *                       A null pointer may be specified to indicate that there
00350 *                       is no restriction.  Otherwise, the magnitude of
00351 *                       cols[0] specifies the length of the array:
00352 *                         cols[0] > 0: the columns are included,
00353 *                         cols[0] < 0: the columns are excluded.
00354 *
00355 *                       For the pixel list keywords TPn_ka and TCn_ka (and
00356 *                       TPCn_ka and TCDn_ka if WCSHDR_LONGKEY is enabled), it
00357 *                       is an error for one column to be selected but not the
00358 *                       other.  This is unlike the situation with invalid
00359 *                       keyrecords, which are simply rejected, because the
00360 *                       error is not intrinsic to the header itself but
00361 *                       arises in the way that it is processed.
00362 *
00363 * Returned:
00364 *   nreject   int*      Number of WCS keywords rejected for syntax errors,
00365 *                       illegal values, etc.  Keywords not recognized as WCS
00366 *                       keywords are simply ignored, refer also to note 5
00367 *                       below.
00368 *
00369 *   nwcs      int*      Number of coordinate representations found.
00370 *
00371 *   wcs       struct wcsprm**
00372 *                       Pointer to an array of wcsprm structs containing up
00373 *                       to 27027 coordinate representations, refer to note 6
00374 *                       below.
00375 *
00376 *                       Memory for the array is allocated by wcsbth() which
00377 *                       also invokes wcsini() for each struct to allocate
```

```
00378 *                       memory for internal arrays and initialize their
00379 *                       members to default values.  Refer also to note 8
00380 *                       below.  Note that wcsset() is not invoked on these
00381 *                       structs.
00382 *
00383 *                       This allocated memory must be freed by the user, first
00384 *                       by invoking wcsfree() for each struct, and then by
00385 *                       freeing the array itself.  A routine, wcsvfree(), is
00386 *                       provided to do this (see below).
00387 *
00388 * Function return value:
00389 *             int       Status return value:
00390 *                         0: Success.
00391 *                         1: Null wcsprm pointer passed.
00392 *                         2: Memory allocation failed.
00393 *                         3: Invalid column selection.
00394 *                         4: Fatal error returned by Flex parser.
00395 *
00396 * Notes:
00397 *   1: wcspih() determines the number of coordinate axes independently for
00398 *      each alternate coordinate representation (denoted by the "a" value in
00399 *      keywords like CTYPEia) from the higher of
00400 *
00401 *        a: NAXIS,
00402 *        b: WCSAXESa,
00403 *        c: The highest axis number in any parameterized WCS keyword.  The
00404 *           keyvalue, as well as the keyword, must be syntactically valid
00405 *           otherwise it will not be considered.
00406 *
00407 *      If none of these keyword types is present, i.e. if the header only
00408 *      contains auxiliary WCS keywords for a particular coordinate
00409 *      representation, then no coordinate description is constructed for it.
00410 *
00411 *      wcsbth() is similar except that it ignores the NAXIS keyword if given
00412 *      an image header to process.
00413 *
00414 *      The number of axes, which is returned as a member of the wcsprm
00415 *      struct, may differ for different coordinate representations of the
00416 *      same image.
00417 *
00418 *   2: wcspih() and wcsbth() enforce correct FITS "keyword = value" syntax
00419 *      with regard to "= " occurring in columns 9 and 10.
00420 *
00421 *      However, they do recognize free-format character (NOST 100-2.0,
00422 *      Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values
00423 *      (Sect. 5.2.4) for all keywords.
00424 *
00425 *   3: Where CROTAn, CDi_ja, and PCi_ja occur together in one header wcspih()
00426 *      and wcsbth() treat them as described in the prologue to wcs.h.
00427 *
00428 *   4: WCS Paper I mistakenly defined the pixel list form of WCSNAMEa as
00429 *      TWCSna instead of WCSNna; the 'T' is meant to substitute for the axis
00430 *      number in the binary table form of the keyword - note that keywords
00431 *      defined in WCS Papers II, III, and VII that are not parameterized by
00432 *      axis number have identical forms for binary tables and pixel lists.
00433 *      Consequently wcsbth() always treats WCSNna and TWCSna as equivalent.
00434 *
00435 *   5: wcspih() and wcsbth() interpret the "relax" argument as a vector of
00436 *      flag bits to provide fine-grained control over what non-standard WCS
00437 *      keywords to accept.  The flag bits are subject to change in future and
00438 *      should be set by using the preprocessor macros (see below) for the
00439 *      purpose.
00440 *
00441 *      - WCSHDR_none: Don't accept any extensions (not even those in the
00442 *              errata).  Treat non-conformant keywords in the same way as
00443 *              non-WCS keywords in the header, i.e. simply ignore them.
00444 *
00445 *      - WCSHDR_all: Accept all extensions recognized by the parser.
00446 *
00447 *      - WCSHDR_reject: Reject non-standard keyrecords (that are not otherwise
00448 *              explicitly accepted by one of the flags below).  A message will
00449 *              optionally be printed on stderr by default, or the stream set
00450 *              by wcsprintf_set(), as determined by the ctrl argument, and
00451 *              nreject will be incremented.
00452 *
00453 *              This flag may be used to signal the presence of non-standard
00454 *              keywords, otherwise they are simply passed over as though they
00455 *              did not exist in the header.  It is mainly intended for testing
00456 *              conformance of a FITS header to the WCS standard.
00457 *
00458 *              Keyrecords may be non-standard in several ways:
00459 *
00460 *                - The keyword may be syntactically valid but with keyvalue of
00461 *                  incorrect type or invalid syntax, or the keycomment may be
00462 *                  malformed.
00463 *
00464 *                - The keyword may strongly resemble a WCS keyword but not, in
```

```
00465 *                  fact, be one because it does not conform to the standard.
00466 *                  For example, "CRPIX01" looks like a CRPIXja keyword, but in
00467 *                  fact the leading zero on the axis number violates the basic
00468 *                  FITS standard.  Likewise, "LONPOLE2" is not a valid
00469 *                  LONPOLEa keyword in the WCS standard, and indeed there is
00470 *                  nothing the parser can sensibly do with it.
00471 *
00472 *                - Use of the keyword may be deprecated by the standard.  Such
00473 *                  will be rejected if not explicitly accepted via one of the
00474 *                  flags below.
00475 *
00476 *      - WCSHDR_strict: As for WCSHDR_reject, but also reject AIPS-convention
00477 *              keywords and all other deprecated usage that is not explicitly
00478 *              accepted.
00479 *
00480 *      - WCSHDR_CROTAia: Accept CROTAia (wcspih()),
00481 *                               iCROTna (wcsbth()),
00482 *                               TCROTna (wcsbth()).
00483 *      - WCSHDR_VELREFa: Accept VELREFa.
00484 *              wcspih() always recognizes the AIPS-convention keywords,
00485 *              CROTAn, EPOCH, and VELREF for the primary representation
00486 *              (a = ' ') but alternates are non-standard.
00487 *
00488 *              wcsbth() accepts EPOCHa and VELREFa only if WCSHDR_AUXIMG is
00489 *              also enabled.
00490 *
00491 *      - WCSHDR_CD00i00j: Accept CD00i00j (wcspih()).
00492 *      - WCSHDR_PC00i00j: Accept PC00i00j (wcspih()).
00493 *      - WCSHDR_PROJPn:   Accept PROJPn   (wcspih()).
00494 *              These appeared in early drafts of WCS Paper I+II (before they
00495 *              were split) and are equivalent to CDi_ja, PCi_ja, and PVi_ma
00496 *              for the primary representation (a = ' ').  PROJPn is
00497 *              equivalent to PVi_ma with m = n <= 9, and is associated
00498 *              exclusively with the latitude axis.
00499 *
00500 *      - WCSHDR_CD0i_0ja: Accept CD0i_0ja (wcspih()).
00501 *      - WCSHDR_PC0i_0ja: Accept PC0i_0ja (wcspih()).
00502 *      - WCSHDR_PV0i_0ma: Accept PV0i_0ja (wcspih()).
00503 *      - WCSHDR_PS0i_0ma: Accept PS0i_0ja (wcspih()).
00504 *              Allow the numerical index to have a leading zero in doubly-
00505 *              parameterized keywords, for example, PC01_01.  WCS Paper I
00506 *              (Sects 2.1.2 & 2.1.4) explicitly disallows leading zeroes.
00507 *              The FITS 3.0 standard document (Sect. 4.1.2.1) states that the
00508 *              index in singly-parameterized keywords (e.g. CTYPEia) "shall
00509 *              not have leading zeroes", and later in Sect. 8.1 that "leading
00510 *              zeroes must not be used" on PVi_ma and PSi_ma.  However, by an
00511 *              oversight, it is silent on PCi_ja and CDi_ja.
00512 *
00513 *      - WCSHDR_DOBSn (wcsbth() only): Allow DOBSn, the column-specific
00514 *              analogue of DATE-OBS.  By an oversight this was never formally
00515 *              defined in the standard.
00516 *
00517 *      - WCSHDR_OBSGLBHn (wcsbth() only): Allow OBSGLn, OBSGBn, and OBSGHn,
00518 *              the column-specific analogues of OBSGEO-L, OBSGEO-B, and
00519 *              OBSGEO-H.  By an oversight these were never formally defined in
00520 *              the standard.
00521 *
00522 *      - WCSHDR_RADECSYS: Accept RADECSYS.  This appeared in early drafts of
00523 *              WCS Paper I+II and was subsequently replaced by RADESYSa.
00524 *
00525 *              wcsbth() accepts RADECSYS only if WCSHDR_AUXIMG is also
00526 *              enabled.
00527 *
00528 *      - WCSHDR_EPOCHa:  Accept EPOCHa.
00529 *
00530 *      - WCSHDR_VSOURCE: Accept VSOURCEa or VSOUna (wcsbth()).  This appeared
00531 *              in early drafts of WCS Paper III and was subsequently dropped
00532 *              in favour of ZSOURCEa and ZSOUna.
00533 *
00534 *              wcsbth() accepts VSOURCEa only if WCSHDR_AUXIMG is also
00535 *              enabled.
00536 *
00537 *      - WCSHDR_DATEREF: Accept DATE-REF, MJD-REF, MJD-REFI, MJD-REFF, JDREF,
00538 *              JD-REFI, and JD-REFF as synonyms for the standard keywords,
00539 *              DATEREF, MJDREF, MJDREFI, MJDREFF, JDREF, JDREFI, and JDREFF.
00540 *              The latter buck the pattern set by the other date keywords
00541 *              ({DATE,MJD}-{OBS,BEG,AVG,END}), thereby increasing the
00542 *              potential for confusion and error.
00543 *
00544 *      - WCSHDR_LONGKEY (wcsbth() only): Accept long forms of the alternate
00545 *              binary table and pixel list WCS keywords, i.e. with "a" non-
00546 *              blank.  Specifically
00547 *
00548 #                jCRPXna  TCRPXna  :  jCRPXn  jCRPna  TCRPXn  TCRPna  CRPIXja
00549 #                   -     TPCn_ka  :    -     ijPCna    -     TPn_ka  PCi_ja
00550 #                   -     TCDn_ka  :    -     ijCDna    -     TCn_ka  CDi_ja
00551 #                iCDLTna  TCDLTna  :  iCDLTn  iCDEna  TCDLTn  TCDEna  CDELTia
```

```
00552 #                 iCUNIna  TCUNIna  :  iCUNIn  iCUNna  TCUNIn  TCUNna  CUNITia
00553 #                 iCTYPna  TCTYPna  :  iCTYPn  iCTYna  TCTYPn  TCTYna  CTYPEia
00554 #                 iCRVLna  TCRVLna  :  iCRVLn  iCRVna  TCRVLn  TCRVna  CRVALia
00555 #                 iPVn_ma  TPVn_ma  :    -     iVn_ma    -     TVn_ma  PVi_ma
00556 #                 iPSn_ma  TPSn_ma  :    -     iSn_ma    -     TSn_ma  PSi_ma
00557 *
00558 *               where the primary and standard alternate forms together with
00559 *               the image-header equivalent are shown rightwards of the colon.
00560 *
00561 *               The long form of these keywords could be described as quasi-
00562 *               standard.  TPCn_ka, iPVn_ma, and TPVn_ma appeared by mistake
00563 *               in the examples in WCS Paper II and subsequently these and
00564 *               also TCDn_ka, iPSn_ma and TPSn_ma were legitimized by the
00565 *               errata to the WCS papers.
00566 *
00567 *               Strictly speaking, the other long forms are non-standard and
00568 *               in fact have never appeared in any draft of the WCS papers nor
00569 *               in the errata.  However, as natural extensions of the primary
00570 *               form they are unlikely to be written with any other intention.
00571 *               Thus it should be safe to accept them provided, of course,
00572 *               that the resulting keyword does not exceed the 8-character
00573 *               limit.
00574 *
00575 *               If WCSHDR_CNAMn is enabled then also accept
00576 *
00577 #                 iCNAMna  TCNAMna  :   ---   iCNAna    ---   TCNAna  CNAMEia
00578 #                 iCRDEna  TCRDEna  :   ---   iCRDna    ---   TCRDna  CRDERia
00579 #                 iCSYEna  TCSYEna  :   ---   iCSYna    ---   TCSYna  CSYERia
00580 #                 iCZPHna  TCZPHna  :   ---   iCZPna    ---   TCZPna  CZPHSia
00581 #                 iCPERna  TCPERna  :   ---   iCPRna    ---   TCPRna  CPERIia
00582 *
00583 *               Note that CNAMEia, CRDERia, CSYERia, CZPHSia, CPERIia, and
00584 *               their variants are not used by WCSLIB but are stored in the
00585 *               wcsprm struct as auxiliary information.
00586 *
00587 *      - WCSHDR_CNAMn (wcsbth() only): Accept iCNAMn, iCRDEn, iCSYEn, iCZPHn,
00588 *               iCPERn, TCNAMn, TCRDEn, TCSYEn, TCZPHn, and TCPERn, i.e. with
00589 *               "a" blank.  While non-standard, these are the obvious analogues
00590 *               of iCTYPn, TCTYPn, etc.
00591 *
00592 *      - WCSHDR_AUXIMG (wcsbth() only): Allow the image-header form of an
00593 *               auxiliary WCS keyword with representation-wide scope to
00594 *               provide a default value for all images.  This default may be
00595 *               overridden by the column-specific form of the keyword.
00596 *
00597 *               For example, a keyword like EQUINOXa would apply to all image
00598 *               arrays in a binary table, or all pixel list columns with
00599 *               alternate representation "a" unless overridden by EQUIna.
00600 *
00601 *               Specifically the keywords are:
00602 *
00603 #                 LONPOLEa  for LONPna
00604 #                 LATPOLEa  for LATPna
00605 #                 VELREF        -       ... (No column-specific form.)
00606 #                 VELREFa       -       ... Only if WCSHDR_VELREFa is set.
00607 *
00608 *               whose keyvalues are actually used by WCSLIB, and also keywords
00609 *               providing auxiliary information that is simply stored in the
00610 *               wcsprm struct:
00611 *
00612 #                 WCSNAMEa  for WCSNna  ... Or TWCSna (see below).
00613 #
00614 #                 DATE-OBS  for DOBSn
00615 #                 MJD-OBS   for MJDOBn
00616 #
00617 #                 RADESYSa  for RADEna
00618 #                 RADECSYS  for RADEna  ... Only if WCSHDR_RADECSYS is set.
00619 #                 EPOCH         -       ... (No column-specific form.)
00620 #                 EPOCHa        -       ... Only if WCSHDR_EPOCHa is set.
00621 #                 EQUINOXa  for EQUIna
00622 *
00623 *               where the image-header keywords on the left provide default
00624 *               values for the column specific keywords on the right.
00625 *
00626 *               Note that, according to Sect. 8.1 of WCS Paper III, and
00627 *               Sect. 5.2 of WCS Paper VII, the following are always inherited:
00628 *
00629 #                 RESTFREQ  for RFRQna
00630 #                 RESTFRQa  for RFRQna
00631 #                 RESTWAVa  for RWAVna
00632 *
00633 *               being those actually used by WCSLIB, together with the
00634 *               following auxiliary keywords, many of which do not have binary
00635 *               table equivalents and therefore can only be inherited:
00636 *
00637 #                 TIMESYS       -
00638 #                 TREFPOS   for TRPOSn
```

```
00639 #                TREFDIR   for TRDIRn
00640 #                PLEPHEM       -
00641 #                TIMEUNIT      -
00642 #                DATEREF       -
00643 #                MJDREF        -
00644 #                MJDREFI       -
00645 #                MJDREFF       -
00646 #                JDREF         -
00647 #                JDREFI        -
00648 #                JDREFF        -
00649 #                TIMEOFFS      -
00650 #
00651 #                DATE-BEG      -
00652 #                DATE-AVG  for DAVGn
00653 #                DATE-END      -
00654 #                MJD-BEG       -
00655 #                MJD-AVG   for MJDAn
00656 #                MJD-END       -
00657 #                JEPOCH        -
00658 #                BEPOCH        -
00659 #                TSTART        -
00660 #                TSTOP         -
00661 #                XPOSURE       -
00662 #                TELAPSE       -
00663 #
00664 #                TIMSYER       -
00665 #                TIMRDER       -
00666 #                TIMEDEL       -
00667 #                TIMEPIXR      -
00668 #
00669 #                OBSGEO-X  for OBSGXn
00670 #                OBSGEO-Y  for OBSGYn
00671 #                OBSGEO-Z  for OBSGZn
00672 #                OBSGEO-L  for OBSGLn
00673 #                OBSGEO-B  for OBSGBn
00674 #                OBSGEO-H  for OBSGHn
00675 #                OBSORBIT      -
00676 #
00677 #                SPECSYSa  for SPECna
00678 #                SSYSOBSa  for SOBSna
00679 #                VELOSYSa  for VSYSna
00680 #                VSOURCEa  for VSOUna  ... Only if WCSHDR_VSOURCE is set.
00681 #                ZSOURCEa  for ZSOUna
00682 #                SSYSSRCa  for SSRCna
00683 #                VELANGLa  for VANGna
00684 *
00685 *              Global image-header keywords, such as MJD-OBS, apply to all
00686 *              alternate representations, and would therefore provide a
00687 *              default value for all images in the header.
00688 *
00689 *              This auxiliary inheritance mechanism applies to binary table
00690 *              image arrays and pixel lists alike.  Most of these keywords
00691 *              have no default value, the exceptions being LONPOLEa and
00692 *              LATPOLEa, and also RADESYSa and EQUINOXa which provide
00693 *              defaults for each other.  Thus one potential difficulty in
00694 *              using WCSHDR_AUXIMG is that of erroneously inheriting one of
00695 *              these four keywords.
00696 *
00697 *              Also, beware of potential inconsistencies that may arise where,
00698 *              for example, DATE-OBS is inherited, but MJD-OBS is overridden
00699 *              by MJDOBn and specifies a different time.  Pairs in this
00700 *              category are:
00701 *
00702 =                   DATE-OBS/DOBSn       versus       MJD-OBS/MJDOBn
00703 =                   DATE-AVG/DAVGn       versus       MJD-AVG/MJDAn
00704 =                   RESTFRQa/RFRQna      versus      RESTWAVa/RWAVna
00705 =                OBSGEO-[XYZ]/OBSG[XYZ]n  versus  OBSGEO-[LBH]/OBSG[LBH]n
00706 *
00707 *              The wcsfixi() routines datfix() and obsfix() are provided to
00708 *              check the consistency of these and other such pairs of
00709 *              keywords.
00710 *
00711 *              Unlike WCSHDR_ALLIMG, the existence of one (or all) of these
00712 *              auxiliary WCS image header keywords will not by itself cause a
00713 *              wcsprm struct to be created for alternate representation "a".
00714 *              This is because they do not provide sufficient information to
00715 *              create a non-trivial coordinate representation when used in
00716 *              conjunction with the default values of those keywords that are
00717 *              parameterized by axis number, such as CTYPEia.
00718 *
00719 *      - WCSHDR_ALLIMG (wcsbth() only): Allow the image-header form of *all*
00720 *              image header WCS keywords to provide a default value for all
00721 *              image arrays in a binary table (n.b. not pixel list).  This
00722 *              default may be overridden by the column-specific form of the
00723 *              keyword.
00724 *
00725 *              For example, a keyword like CRPIXja would apply to all image
```

```
00726 *              arrays in a binary table with alternate representation "a"
00727 *              unless overridden by jCRPna.
00728 *
00729 *              Specifically the keywords are those listed above for
00730 *              WCSHDR_AUXIMG plus
00731 *
00732 #                WCSAXESa  for WCAXna
00733 *
00734 *              which defines the coordinate dimensionality, and the following
00735 *              keywords that are parameterized by axis number:
00736 *
00737 #                CRPIXja   for jCRPna
00738 #                PCi_ja    for ijPCna
00739 #                CDi_ja    for ijCDna
00740 #                CDELTia   for iCDEna
00741 #                CROTAi    for iCROTn
00742 #                CROTAia       -      ... Only if WCSHDR_CROTAia is set.
00743 #                CUNITia   for iCUNna
00744 #                CTYPEia   for iCTYna
00745 #                CRVALia   for iCRVna
00746 #                PVi_ma    for iVn_ma
00747 #                PSi_ma    for iSn_ma
00748 #
00749 #                CNAMEia   for iCNAna
00750 #                CRDERia   for iCRDna
00751 #                CSYERia   for iCSYna
00752 #                CZPHSia   for iCZPna
00753 #                CPERIia   for iCPRna
00754 *
00755 *              where the image-header keywords on the left provide default
00756 *              values for the column specific keywords on the right.
00757 *
00758 *              This full inheritance mechanism only applies to binary table
00759 *              image arrays, not pixel lists, because in the latter case
00760 *              there is no well-defined association between coordinate axis
00761 *              number and column number (see note 9 below).
00762 *
00763 *              Note that CNAMEia, CRDERia, CSYERia, and their variants are
00764 *              not used by WCSLIB but are stored in the wcsprm struct as
00765 *              auxiliary information.
00766 *
00767 *              Note especially that at least one wcsprm struct will be
00768 *              returned for each "a" found in one of the image header
00769 *              keywords listed above:
00770 *
00771 *              - If the image header keywords for "a" ARE NOT inherited by a
00772 *                binary table, then the struct will not be associated with
00773 *                any particular table column number and it is up to the user
00774 *                to provide an association.
00775 *
00776 *              - If the image header keywords for "a" ARE inherited by a
00777 *                binary table image array, then those keywords are considered
00778 *                to be "exhausted" and do not result in a separate wcsprm
00779 *                struct.
00780 *
00781 *      For example, to accept CD00i00j and PC00i00j and reject all other
00782 *      extensions, use
00783 *
00784 =        relax = WCSHDR_reject | WCSHDR_CD00i00j | WCSHDR_PC00i00j;
00785 *
00786 *      The parser always treats EPOCH as subordinate to EQUINOXa if both are
00787 *      present, and VSOURCEa is always subordinate to ZSOURCEa.
00788 *
00789 *      Likewise, VELREF is subordinate to the formalism of WCS Paper III, see
00790 *      spcaips().
00791 *
00792 *      Neither wcspih() nor wcsbth() currently recognize the AIPS-convention
00793 *      keywords ALTRPIX or ALTRVAL which effectively define an alternative
00794 *      representation for a spectral axis.
00795 *
00796 *    6: Depending on what flags have been set in its "relax" argument,
00797 *      wcsbth() could return as many as 27027 wcsprm structs:
00798 *
00799 *      - Up to 27 unattached representations derived from image header
00800 *        keywords.
00801 *
00802 *      - Up to 27 structs for each of up to 999 columns containing an image
00803 *        arrays.
00804 *
00805 *      - Up to 27 structs for a pixel list.
00806 *
00807 *      Note that it is considered legitimate for a column to contain an image
00808 *      array and also form part of a pixel list, and in particular that
00809 *      wcsbth() does not check the TFORM keyword for a pixel list column to
00810 *      check that it is scalar.
00811 *
00812 *      In practice, of course, a realistic binary table header is unlikely to
```

```
00813 *      contain more than a handful of images.
00814 *
00815 *      In order for wcsbth() to create a wcsprm struct for a particular
00816 *      coordinate representation, at least one WCS keyword that defines an
00817 *      axis number must be present, either directly or by inheritance if
00818 *      WCSHDR_ALLIMG is set.
00819 *
00820 *      When the image header keywords for an alternate representation are
00821 *      inherited by a binary table image array via WCSHDR_ALLIMG, those
00822 *      keywords are considered to be "exhausted" and do not result in a
00823 *      separate wcsprm struct.  Otherwise they do.
00824 *
00825 *   7: Neither wcspih() nor wcsbth() check for duplicated keywords, in most
00826 *      cases they accept the last encountered.
00827 *
00828 *   8: wcspih() and wcsbth() use wcsnpv() and wcsnps() (refer to the prologue
00829 *      of wcs.h) to match the size of the pv[] and ps[] arrays in the wcsprm
00830 *      structs to the number in the header.  Consequently there are no unused
00831 *      elements in the pv[] and ps[] arrays, indeed they will often be of
00832 *      zero length.
00833 *
00834 *   9: The FITS WCS standard for pixel lists assumes that a pixel list
00835 *      defines one and only one image, i.e. that each row of the binary table
00836 *      refers to just one event, e.g. the detection of a single photon or
00837 *      neutrino, for which the device "pixel" coordinates are stored in
00838 *      separate scalar columns of the table.
00839 *
00840 *      In the absence of a standard for pixel lists - or even an informal
00841 *      description! - let alone a formal mechanism for identifying the columns
00842 *      containing pixel coordinates (as opposed to pixel values or metadata
00843 *      recorded at the time the photon or neutrino was detected), WCS Paper I
00844 *      discusses how the WCS keywords themselves may be used to identify them.
00845 *
00846 *      In practice, however, pixel lists have been used to store multiple
00847 *      images.  Besides not specifying how to identify columns, the pixel list
00848 *      convention is also silent on the method to be used to associate table
00849 *      columns with image axes.
00850 *
00851 *      An additional shortcoming is the absence of a formal method for
00852 *      associating global binary-table WCS keywords, such as WCSNna or MJDOBn,
00853 *      with a pixel list image, whether one or several.
00854 *
00855 *      In light of these uncertainties, wcsbth() simply collects all WCS
00856 *      keywords for a particular pixel list coordinate representation (i.e.
00857 *      the "a" value in TCTYna) into one wcsprm struct.  However, these
00858 *      alternates need not be associated with the same table columns and this
00859 *      allows a pixel list to contain up to 27 separate images.  As usual, if
00860 *      one of these representations happened to contain more than two
00861 *      celestial axes, for example, then an error would result when wcsset()
00862 *      is invoked on it.  In this case the "colsel" argument could be used to
00863 *      restrict the columns used to construct the representation so that it
00864 *      only contained one pair of celestial axes.
00865 *
00866 *      Global, binary-table WCS keywords are considered to apply to the pixel
00867 *      list image with matching alternate (e.g. the "a" value in LONPna or
00868 *      EQUIna), regardless of the table columns the image occupies.  In other
00869 *      words, the column number is ignored (the "n" value in LONPna or
00870 *      EQUIna).  This also applies for global, binary-table WCS keywords that
00871 *      have no alternates, such as MJDOBn and OBSGXn, which match all images
00872 *      in a pixel list.  Take heed that this may lead to counterintuitive
00873 *      behaviour, especially where such a keyword references a column that
00874 *      does not store pixel coordinates, and moreso where the pixel list
00875 *      stores only a single image.  In fact, as the column number, n, is
00876 *      ignored for such keywords, it would make no difference even if they
00877 *      referenced non-existent columns.  Moreover, there is no requirement for
00878 *      consistency in the column numbers used for such keywords, even for
00879 *      OBSGXn, OBSGYn, and OBSGZn which are meant to define the elements of a
00880 *      coordinate vector.  Although it would surely be perverse to construct a
00881 *      pixel list like this, such a situation may still arise in practice
00882 *      where columns are deleted from a binary table.
00883 *
00884 *      The situation with global, binary-table WCS keywords becomes
00885 *      potentially even more confusing when image arrays and pixel list images
00886 *      coexist in one binary table.  In that case, a keyword such as MJDOBn
00887 *      may legitimately appear multiple times with n referencing different
00888 *      image arrays.  Which then is the one that applies to the pixel list
00889 *      images?  In this implementation, it is the last instance that appears
00890 *      in the header, whether or not it is also associated with an image
00891 *      array.
00892 *
00893 *
00894 * wcstab() - Tabular construction routine
00895 * --------------------------------------
00896 * wcstab() assists in filling in the information in the wcsprm struct relating
00897 * to coordinate lookup tables.
00898 *
00899 * Tabular coordinates ('TAB') present certain difficulties in that the main
```

```
00900 * components of the lookup table - the multidimensional coordinate array plus
00901 * an index vector for each dimension - are stored in a FITS binary table
00902 * extension (BINTABLE).  Information required to locate these arrays is stored
00903 * in PVi_ma and PSi_ma keywords in the image header.
00904 *
00905 * wcstab() parses the PVi_ma and PSi_ma keywords associated with each 'TAB'
00906 * axis and allocates memory in the wcsprm struct for the required number of
00907 * tabprm structs.  It sets as much of the tabprm struct as can be gleaned from
00908 * the image header, and also sets up an array of wtbarr structs (described in
00909 * the prologue of wtbarr.h) to assist in extracting the required arrays from
00910 * the BINTABLE extension(s).
00911 *
00912 * It is then up to the user to allocate memory for, and copy arrays from the
00913 * BINTABLE extension(s) into the tabprm structs.  A CFITSIO routine,
00914 * fits_read_wcstab(), has been provided for this purpose, see getwcstab.h.
00915 * wcsset() will automatically take control of this allocated memory, in
00916 * particular causing it to be freed by wcsfree(); the user must not attempt
00917 * to free it after wcsset() has been called.
00918 *
00919 * Note that wcspih() and wcsbth() automatically invoke wcstab() on each of the
00920 * wcsprm structs that they return.
00921 *
00922 * Given and returned:
00923 *   wcs       struct wcsprm*
00924 *                       Coordinate transformation parameters (see below).
00925 *
00926 *                       wcstab() sets ntab, tab, nwtb and wtb, allocating
00927 *                       memory for the tab and wtb arrays.  This allocated
00928 *                       memory will be freed automatically by wcsfree().
00929 *
00930 * Function return value:
00931 *             int       Status return value:
00932 *                         0: Success.
00933 *                         1: Null wcsprm pointer passed.
00934 *                         2: Memory allocation failed.
00935 *                         3: Invalid tabular parameters.
00936 *
00937 *                       For returns > 1, a detailed error message is set in
00938 *                       wcsprm::err if enabled, see wcserr_enable().
00939 *
00940 *
00941 * wcsidx() - Index alternate coordinate representations
00942 * -----------------------------------------------------
00943 * wcsidx() returns an array of 27 indices for the alternate coordinate
00944 * representations in the array of wcsprm structs returned by wcspih().  For
00945 * the array returned by wcsbth() it returns indices for the unattached
00946 * (colnum == 0) representations derived from image header keywords - use
00947 * wcsbdx() for those derived from binary table image arrays or pixel lists
00948 * keywords.
00949 *
00950 * Given:
00951 *   nwcs      int       Number of coordinate representations in the array.
00952 *
00953 *   wcs       const struct wcsprm**
00954 *                       Pointer to an array of wcsprm structs returned by
00955 *                       wcspih() or wcsbth().
00956 *
00957 * Returned:
00958 *   alts      int[27]   Index of each alternate coordinate representation in
00959 *                       the array: alts[0] for the primary, alts[1] for 'A',
00960 *                       etc., set to -1 if not present.
00961 *
00962 *                       For example, if there was no 'P' representation then
00963 *
00964 =                         alts['P'-'A'+1] == -1;
00965 *
00966 *                       Otherwise, the address of its wcsprm struct would be
00967 *
00968 =                         wcs + alts['P'-'A'+1];
00969 *
00970 * Function return value:
00971 *             int       Status return value:
00972 *                         0: Success.
00973 *                         1: Null wcsprm pointer passed.
00974 *
00975 *
00976 * wcsbdx() - Index alternate coordinate represention
00977 * --------------------------------------------------
00978 * wcsbdx() returns an array of 999 x 27 indices for the alternate coordinate
00979 * representions for binary table image arrays xor pixel lists in the array of
00980 * wcsprm structs returned by wcsbth().  Use wcsidx() for the unattached
00981 * representations derived from image header keywords.
00982 *
00983 * Given:
00984 *   nwcs      int       Number of coordinate representations in the array.
00985 *
00986 *   wcs       const struct wcsprm**
```

```
00987 *                      Pointer to an array of wcsprm structs returned by
00988 *                      wcsbth().
00989 *
00990 *   type      int      Select the type of coordinate representation:
00991 *                        0: binary table image arrays,
00992 *                        1: pixel lists.
00993 *
00994 * Returned:
00995 *   alts      short[1000][28]
00996 *                      Index of each alternate coordinate represention in the
00997 *                      array: alts[col][0] for the primary, alts[col][1] for
00998 *                      'A', to alts[col][26] for 'Z', where col is the
00999 *                      1-relative column number, and col == 0 is used for
01000 *                      unattached image headers.  Set to -1 if not present.
01001 *
01002 *                      alts[col][27] counts the number of coordinate
01003 *                      representations of the chosen type for each column.
01004 *
01005 *                      For example, if there was no 'P' represention for
01006 *                      column 13 then
01007 *
01008 =                        alts[13]['P'-'A'+1] == -1;
01009 *
01010 *                      Otherwise, the address of its wcsprm struct would be
01011 *
01012 =                        wcs + alts[13]['P'-'A'+1];
01013 *
01014 * Function return value:
01015 *             int      Status return value:
01016 *                        0: Success.
01017 *                        1: Null wcsprm pointer passed.
01018 *
01019 *
01020 * wcsvfree() - Free the array of wcsprm structs
01021 * ---------------------------------------------
01022 * wcsvfree() frees the memory allocated by wcspih() or wcsbth() for the array
01023 * of wcsprm structs, first invoking wcsfree() on each of the array members.
01024 *
01025 * Given and returned:
01026 *   nwcs      int*     Number of coordinate representations found; set to 0
01027 *                      on return.
01028 *
01029 *   wcs       struct wcsprm**
01030 *                      Pointer to the array of wcsprm structs; set to 0x0 on
01031 *                      return.
01032 *
01033 * Function return value:
01034 *             int      Status return value:
01035 *                        0: Success.
01036 *                        1: Null wcsprm pointer passed.
01037 *
01038 *
01039 * wcshdo() - Write out a wcsprm struct as a FITS header
01040 * -----------------------------------------------------
01041 * wcshdo() translates a wcsprm struct into a FITS header.  If the colnum
01042 * member of the struct is non-zero then a binary table image array header will
01043 * be produced.  Otherwise, if the colax[] member of the struct is set non-zero
01044 * then a pixel list header will be produced.  Otherwise, a primary image or
01045 * image extension header will be produced.
01046 *
01047 * If the struct was originally constructed from a header, e.g. by wcspih(),
01048 * the output header will almost certainly differ in a number of respects:
01049 *
01050 *   - The output header only contains WCS-related keywords.  In particular, it
01051 *     does not contain syntactically-required keywords such as SIMPLE, NAXIS,
01052 *     BITPIX, or END.
01053 *
01054 *   - Elements of the PCi_ja matrix will be written if and only if they differ
01055 *     from the unit matrix.  Thus, if the matrix is unity then no elements
01056 *     will be written.
01057 *
01058 *   - The redundant keywords MJDREF, JDREF, JDREFI, JDREFF, all of which
01059 *     duplicate MJDREFI + MJDREFF, are never written.  OBSGEO-[LBH] are not
01060 *     written if OBSGEO-[XYZ] are defined.
01061 *
01062 *   - Deprecated (e.g. CROTAn, RESTFREQ, VELREF, RADECSYS, EPOCH, VSOURCEa) or
01063 *     non-standard usage will be translated to standard (this is partially
01064 *     dependent on whether wcsfix() was applied).
01065 *
01066 *   - Additional keywords such as WCSAXESa, CUNITia, LONPOLEa and LATPOLEa may
01067 *     appear.
01068 *
01069 *   - Quantities will be converted to the units used internally, basically SI
01070 *     with the addition of degrees.
01071 *
01072 *   - Floating-point quantities may be given to a different decimal precision.
01073 *
```

```
01074 *   - The original keycomments will be lost, although wcshdo() tries hard to
01075 *     write meaningful comments.
01076 *
01077 *   - Keyword order will almost certainly be changed.
01078 *
01079 * Keywords can be translated between the image array, binary table, and pixel
01080 * lists forms by manipulating the colnum or colax[] members of the wcsprm
01081 * struct.
01082 *
01083 * Given:
01084 *   ctrl      int       Vector of flag bits that controls the degree of
01085 *                       permissiveness in departing from the published WCS
01086 *                       standard, and also controls the formatting of
01087 *                       floating-point keyvalues.  Set it to zero to get the
01088 *                       default behaviour.
01089 *
01090 *                       Flag bits for the degree of permissiveness:
01091 *                         WCSHDO_none: Recognize only FITS keywords defined by
01092 *                            the published WCS standard.
01093 *                         WCSHDO_all: Admit all recognized informal extensions
01094 *                            of the WCS standard.
01095 *                       Fine-grained control of the degree of permissiveness
01096 *                       is also possible as explained in the notes below.
01097 *
01098 *                       As for controlling floating-point formatting, by
01099 *                       default wcshdo() uses "%20.12G" for non-parameterized
01100 *                       keywords such as LONPOLEa, and attempts to make the
01101 *                       header more human-readable by using the same "%f"
01102 *                       format for all values of each of the following
01103 *                       parameterized keywords: CRPIXja, PCi_ja, and CDELTia
01104 *                       (n.b. excluding CRVALia).  Each has the same field
01105 *                       width and precision so that the decimal points line
01106 *                       up.  The precision, allowing for up to 15 significant
01107 *                       digits, is chosen so that there are no excess trailing
01108 *                       zeroes.  A similar formatting scheme applies by
01109 *                       default for distortion function parameters.
01110 *
01111 *                       However, where the values of, for example, CDELTia
01112 *                       differ by many orders of magnitude, the default
01113 *                       formatting scheme may cause unacceptable loss of
01114 *                       precision for the lower-valued keyvalues.  Thus the
01115 *                       default behaviour may be overridden:
01116 *                         WCSHDO_P12: Use "%20.12G" format for all floating-
01117 *                            point keyvalues (12 significant digits).
01118 *                         WCSHDO_P13: Use "%21.13G" format for all floating-
01119 *                            point keyvalues (13 significant digits).
01120 *                         WCSHDO_P14: Use "%22.14G" format for all floating-
01121 *                            point keyvalues (14 significant digits).
01122 *                         WCSHDO_P15: Use "%23.15G" format for all floating-
01123 *                            point keyvalues (15 significant digits).
01124 *                         WCSHDO_P16: Use "%24.16G" format for all floating-
01125 *                            point keyvalues (16 significant digits).
01126 *                         WCSHDO_P17: Use "%25.17G" format for all floating-
01127 *                            point keyvalues (17 significant digits).
01128 *                       If more than one of the above flags are set, the
01129 *                       highest number of significant digits prevails.  In
01130 *                       addition, there is an anciliary flag:
01131 *                         WCSHDO_EFMT: Use "%E" format instead of the default
01132 *                            "%G" format above.
01133 *                       Note that excess trailing zeroes are stripped off the
01134 *                       fractional part with "%G" (which never occurs with
01135 *                       "%E").  Note also that the higher-precision options
01136 *                       eat into the keycomment area.  In this regard,
01137 *                       WCSHDO_P14 causes minimal disruption with "%G" format,
01138 *                       while WCSHDO_P13 is appropriate with "%E".
01139 *
01140 * Given and returned:
01141 *   wcs       struct wcsprm*
01142 *                       Pointer to a wcsprm struct containing coordinate
01143 *                       transformation parameters.  Will be initialized if
01144 *                       necessary.
01145 *
01146 * Returned:
01147 *   nkeyrec   int*      Number of FITS header keyrecords returned in the
01148 *                       "header" array.
01149 *
01150 *   header    char**    Pointer to an array of char holding the header.
01151 *                       Storage for the array is allocated by wcshdo() in
01152 *                       blocks of 2880 bytes (32 x 80-character keyrecords)
01153 *                       and must be freed by the user to avoid memory leaks.
01154 *                       See wcsdealloc().
01155 *
01156 *                       Each keyrecord is 80 characters long and is *NOT*
01157 *                       null-terminated, so the first keyrecord starts at
01158 *                       (*header)[0], the second at (*header)[80], etc.
01159 *
01160 * Function return value:
```

```
01161 *             int       Status return value (associated with wcs_errmsg[]):
01162 *                         0: Success.
01163 *                         1: Null wcsprm pointer passed.
01164 *                         2: Memory allocation failed.
01165 *                         3: Linear transformation matrix is singular.
01166 *                         4: Inconsistent or unrecognized coordinate axis
01167 *                            types.
01168 *                         5: Invalid parameter value.
01169 *                         6: Invalid coordinate transformation parameters.
01170 *                         7: Ill-conditioned coordinate transformation
01171 *                            parameters.
01172 *
01173 *                       For returns > 1, a detailed error message is set in
01174 *                       wcsprm::err if enabled, see wcserr_enable().
01175 *
01176 * Notes:
01177 *   1: wcshdo() interprets the "relax" argument as a vector of flag bits to
01178 *      provide fine-grained control over what non-standard WCS keywords to
01179 *      write.  The flag bits are subject to change in future and should be set
01180 *      by using the preprocessor macros (see below) for the purpose.
01181 *
01182 *      - WCSHDO_none: Don't use any extensions.
01183 *
01184 *      - WCSHDO_all: Write all recognized extensions, equivalent to setting
01185 *              each flag bit.
01186 *
01187 *      - WCSHDO_safe: Write all extensions that are considered to be safe and
01188 *              recommended.
01189 *
01190 *      - WCSHDO_DOBSn: Write DOBSn, the column-specific analogue of DATE-OBS
01191 *              for use in binary tables and pixel lists.  WCS Paper III
01192 *              introduced DATE-AVG and DAVGn but by an oversight DOBSn (the
01193 *              obvious analogy) was never formally defined by the standard.
01194 *              The alternative to using DOBSn is to write DATE-OBS which
01195 *              applies to the whole table.  This usage is considered to be
01196 *              safe and is recommended.
01197 *
01198 *      - WCSHDO_TPCn_ka: WCS Paper I defined
01199 *
01200 *              - TPn_ka and TCn_ka for pixel lists
01201 *
01202 *              but WCS Paper II uses TPCn_ka in one example and subsequently
01203 *              the errata for the WCS papers legitimized the use of
01204 *
01205 *              - TPCn_ka and TCDn_ka for pixel lists
01206 *
01207 *              provided that the keyword does not exceed eight characters.
01208 *              This usage is considered to be safe and is recommended because
01209 *              of the non-mnemonic terseness of the shorter forms.
01210 *
01211 *      - WCSHDO_PVn_ma: WCS Paper I defined
01212 *
01213 *              - iVn_ma and iSn_ma for bintables and
01214 *              - TVn_ma and TSn_ma for pixel lists
01215 *
01216 *              but WCS Paper II uses iPVn_ma and TPVn_ma in the examples and
01217 *              subsequently the errata for the WCS papers legitimized the use
01218 *              of
01219 *
01220 *              - iPVn_ma and iPSn_ma for bintables and
01221 *              - TPVn_ma and TPSn_ma for pixel lists
01222 *
01223 *              provided that the keyword does not exceed eight characters.
01224 *              This usage is considered to be safe and is recommended because
01225 *              of the non-mnemonic terseness of the shorter forms.
01226 *
01227 *      - WCSHDO_CRPXna: For historical reasons WCS Paper I defined
01228 *
01229 *              - jCRPXn, iCDLTn, iCUNIn, iCTYPn, and iCRVLn for bintables and
01230 *              - TCRPXn, TCDLTn, TCUNIn, TCTYPn, and TCRVLn for pixel lists
01231 *
01232 *              for use without an alternate version specifier.  However,
01233 *              because of the eight-character keyword constraint, in order to
01234 *              accommodate column numbers greater than 99 WCS Paper I also
01235 *              defined
01236 *
01237 *              - jCRPna, iCDEna, iCUNna, iCTYna and iCRVna for bintables and
01238 *              - TCRPna, TCDEna, TCUNna, TCTYna and TCRVna for pixel lists
01239 *
01240 *              for use with an alternate version specifier (the "a").  Like
01241 *              the PC, CD, PV, and PS keywords there is an obvious tendency to
01242 *              confuse these two forms for column numbers up to 99.  It is
01243 *              very unlikely that any parser would reject keywords in the
01244 *              first set with a non-blank alternate version specifier so this
01245 *              usage is considered to be safe and is recommended.
01246 *
01247 *      - WCSHDO_CNAMna: WCS Papers I and III defined
```

```
01248 *
01249 *              - iCNAna,  iCRDna,  and iCSYna  for bintables and
01250 *              - TCNAna,  TCRDna,  and TCSYna  for pixel lists
01251 *
01252 *              By analogy with the above, the long forms would be
01253 *
01254 *              - iCNAMna, iCRDEna, and iCSYEna for bintables and
01255 *              - TCNAMna, TCRDEna, and TCSYEna for pixel lists
01256 *
01257 *              Note that these keywords provide auxiliary information only,
01258 *              none of them are needed to compute world coordinates.  This
01259 *              usage is potentially unsafe and is not recommended at this
01260 *              time.
01261 *
01262 *      - WCSHDO_WCSNna: In light of wcsbth() note 4, write WCSNna instead of
01263 *              TWCSna for pixel lists.  While wcsbth() treats WCSNna and
01264 *              TWCSna as equivalent, other parsers may not.  Consequently,
01265 *              this usage is potentially unsafe and is not recommended at this
01266 *              time.
01267 *
01268 *
01269 * Global variable: const char *wcshdr_errmsg[] - Status return messages
01270 * ---------------------------------------------------------------------
01271 * Error messages to match the status value returned from each function.
01272 * Use wcs_errmsg[] for status returns from wcshdo().
01273 *

  Macro used to test for an undefined quantity.

6.31.1 Detailed Description

Definition of mathematical constants used by WCSLIB.

6.31.2 Macro Definition Documentation

PI

```
#define PI 3.14159265358979323846264 3
```

D2R

```
#define D2R PI/180.0
```

Degrees to radians conversion factor.

Factor $\pi/180^\circ$ to convert from degrees to radians.

R2D

```
#define R2D 180.0/PI
```

Radians to degrees conversion factor.

Factor $180^\circ/\pi$ to convert from radians to degrees.

SQRT2

```
#define SQRT2 1.4142135623730950488
```

$\sqrt{2}$, used only by molset() (**MOL** projection).

SQRT2INV

```
#define SQRT2INV 1.0/SQRT2
```

$1/\sqrt{2}$, used only by qscx2s() (**QSC** projection).

UNDEFINED

```
#define UNDEFINED 987654321.0e99
```

Value used to indicate an undefined quantity.

Value used to indicate an undefined quantity (noting that NaNs cannot be used portably).

undefined

```
#define undefined(
              value ) (value == UNDEFINED)
```

Macro used to test for an undefined quantity.

Macro used to test for an undefined value.

6.33 wcsprintf.h File Reference

```
#include <inttypes.h>
#include <stdio.h>
```

Macros

- #define WCSPRINTF_PTR(str1, ptr, str2)

  Print addresses in a consistent way.

Functions

- int wcsprintf_set (FILE *wcsout)

  Set output disposition for wcsprintf() and wcsfprintf().
- int wcsprintf (const char *format,...)

  Print function used by WCSLIB diagnostic routines.
- int wcsfprintf (FILE *stream, const char *format,...)

  Print function used by WCSLIB diagnostic routines.
- const char * wcsprintf_buf (void)

  Get the address of the internal string buffer.

6.33.1 Detailed Description

Routines in this suite allow diagnostic output from celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcserr_prt() to be redirected to a file or captured in a string buffer. Those routines all use wcsprintf() for output. Likewise wcsfprintf() is used by wcsbth() and wcspih(). Both functions may be used by application programmers to have other output go to the same place.

6.33.2 Macro Definition Documentation

WCSPRINTF_PTR

```
#define WCSPRINTF_PTR(
              str1,
              ptr,
              str2 )
```

Value:

```
  if (ptr) { \
    wcsprintf("%s%#" PRIxPTR "%s", (str1), (uintptr_t)(ptr), (str2)); \
  } else { \
    wcsprintf("%s0x0%s", (str1), (str2)); \
  }
```

Print addresses in a consistent way.

WCSPRINTF_PTR() is a preprocessor macro used to print addresses in a consistent way.

On some systems the "p" format descriptor renders a NULL pointer as the string "0x0". On others, however, it produces "0" or even "(nil)". On some systems a non-zero address is prefixed with "0x", on others, not.

The **WCSPRINTF_PTR**() macro ensures that a NULL pointer is always rendered as "0x0" and that non-zero addresses are prefixed with "0x" thus providing consistency, for example, for comparing the output of test programs.

6.33.3 Function Documentation

wcsprintf_set()

```
int wcsprintf_set (
             FILE * wcsout )
```

Set output disposition for wcsprintf() and wcsfprintf().

wcsprintf_set() sets the output disposition for wcsprintf() which is used by the celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcserr_prt() routines, and for wcsfprintf() which is used by wcsbth() and wcspih().

Parameters

in	*wcsout*	Pointer to an output stream that has been opened for writing, e.g. by the fopen() stdio library function, or one of the predefined stdio output streams - stdout and stderr. If zero (NULL), output is written to an internally-allocated string buffer, the address of which may be obtained by wcsprintf_buf().

Returns

Status return value:

- 0: Success.

wcsprintf()

```
int wcsprintf (
            const char * format,
             ...  )
```

Print function used by WCSLIB diagnostic routines.

wcsprintf() is used by celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcserr_prt() for diagnostic output which by default goes to stdout. However, it may be redirected to a file or string buffer via **wcsprintf_set**().

Parameters

in	*format*	Format string, passed to one of the printf(3) family of stdio library functions.
in	...	Argument list matching format, as per printf(3).

Returns

Number of bytes written.

wcsfprintf()

```
int wcsfprintf (
            FILE * stream,
            const char * format,
             ...  )
```

Print function used by WCSLIB diagnostic routines.

wcsfprintf() is used by wcsbth(), and wcspih() for diagnostic output which they send to stderr. However, it may be redirected to a file or string buffer via wcsprintf_set().

Parameters

in	*stream*	The output stream if not overridden by a call to wcsprintf_set().
in	*format*	Format string, passed to one of the printf(3) family of stdio library functions.
in	...	Argument list matching format, as per printf(3).

Returns

Number of bytes written.

wcsprintf_buf()

```
wcsprintf_buf (
             void  )
```

Get the address of the internal string buffer.

wcsprintf_buf() returns the address of the internal string buffer created when wcsprintf_set() is invoked with its FILE* argument set to zero.

Returns

Address of the internal string buffer. The user may free this buffer by calling wcsprintf_set() with a valid FILE*, e.g. stdout. The free() stdlib library function must NOT be invoked on this const pointer.

6.35 wcstrig.h File Reference

```
#include <math.h>
#include "wcsconfig.h"
```

Macros

- #define WCSTRIG_TOL 1e-10

  Domain tolerance for asin() and acos() functions.

Functions

- double cosd (double angle)

  Cosine of an angle in degrees.
- double sind (double angle)

  Sine of an angle in degrees.
- void sincosd (double angle, double *sin, double *cos)

  Sine and cosine of an angle in degrees.
- double tand (double angle)

  Tangent of an angle in degrees.
- double acosd (double x)

  Inverse cosine, returning angle in degrees.
- double asind (double y)

  Inverse sine, returning angle in degrees.
- double atand (double s)

  Inverse tangent, returning angle in degrees.
- double atan2d (double y, double x)

  Polar angle of (x, y), in degrees.

6.35.1 Detailed Description

When dealing with celestial coordinate systems and spherical projections (some moreso than others) it is often desirable to use an angular measure that provides an exact representation of the latitude of the north or south pole. The WCSLIB routines use the following trigonometric functions that take or return angles in degrees:

- cosd()
- sind()

- tand()
- acosd()
- asind()
- atand()
- atan2d()
- sincosd()

These "trigd" routines are expected to handle angles that are a multiple of 90° returning an exact result. Some C implementations provide these as part of a system library and in such cases it may (or may not!) be preferable to use them. WCSLIB provides wrappers on the standard trig functions based on radian measure, adding tests for multiples of 90°.

However, wcstrig.h also provides the choice of using preprocessor macro implementations of the trigd functions that don't test for multiples of 90° (compile with -DWCSTRIG_MACRO). These are typically 20% faster but may lead to problems near the poles.

6.35.2 Macro Definition Documentation

WCSTRIG_TOL

```
#define WCSTRIG_TOL 1e-10
```

Domain tolerance for asin() and acos() functions.

Domain tolerance for the asin() and acos() functions to allow for floating point rounding errors.

If v lies in the range $1 < |v| < 1 + WCSTRIG\_TOL$ then it will be treated as $|v| == 1$.

6.35.3 Function Documentation

cosd()

```
double cosd (
            double angle )
```

Cosine of an angle in degrees.

cosd() returns the cosine of an angle given in degrees.

Parameters

in	*angle*	[deg].

Returns

Cosine of the angle.

sind()

```
double sind (
            double angle )
```

Sine of an angle in degrees.

sind() returns the sine of an angle given in degrees.

Parameters

in	*angle*	[deg].

Returns

Sine of the angle.

sincosd()

```
void sincosd (
            double angle,
            double * sin,
            double * cos )
```

Sine and cosine of an angle in degrees.

sincosd() returns the sine and cosine of an angle given in degrees.

Parameters

in	*angle*	[deg].
out	*sin*	Sine of the angle.
out	*cos*	Cosine of the angle.

Returns

tand()

```
double tand (
            double angle )
```

Tangent of an angle in degrees.

tand() returns the tangent of an angle given in degrees.

Parameters

in	*angle*	[deg].

Returns

Tangent of the angle.

acosd()

```
double acosd (
             double x )
```

Inverse cosine, returning angle in degrees.

acosd() returns the inverse cosine in degrees.

Parameters

in	*x*	in the range [-1,1].

Returns

Inverse cosine of x [deg].

asind()

```
double asind (
             double y )
```

Inverse sine, returning angle in degrees.

asind() returns the inverse sine in degrees.

Parameters

in	*y*	in the range [-1,1].

Returns

Inverse sine of y [deg].

atand()

```
double atand (
             double s )
```

Inverse tangent, returning angle in degrees.

atand() returns the inverse tangent in degrees.

Parameters

in	*s*	

Returns

Inverse tangent of s [deg].

atan2d()

```
double atan2d (
              double y,
              double x )
```

Polar angle of (x, y), in degrees.

atan2d() returns the polar angle, β, in degrees, of polar coordinates (ρ, β) corresponding to Cartesian coordinates (x, y). It is equivalent to the $\arg(x, y)$ function of WCS Paper II, though with transposed arguments.

Parameters

in	*y*	Cartesian y-coordinate.
in	*x*	Cartesian x-coordinate.

Returns

Polar angle of (x, y) [deg].

00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wcstrig routines
```

```
00031 * ------------------------------
00032 * When dealing with celestial coordinate systems and spherical projections
00033 * (some moreso than others) it is often desirable to use an angular measure
00034 * that provides an exact representation of the latitude of the north or south
00035 * pole.  The WCSLIB routines use the following trigonometric functions that
00036 * take or return angles in degrees:
00037 *
00038 *   - cosd()
00039 *   - sind()
00040 *   - tand()
00041 *   - acosd()
00042 *   - asind()
00043 *   - atand()
00044 *   - atan2d()
00045 *   - sincosd()
00046 *
00047 * These "trigd" routines are expected to handle angles that are a multiple of
00048 * 90 degrees returning an exact result.  Some C implementations provide these
00049 * as part of a system library and in such cases it may (or may not!) be
00050 * preferable to use them.  WCSLIB provides wrappers on the standard trig
00051 * functions based on radian measure, adding tests for multiples of 90 degrees.
00052 *
00053 * However, wcstrig.h also provides the choice of using preprocessor macro
00054 * implementations of the trigd functions that don't test for multiples of
00055 * 90 degrees (compile with -DWCSTRIG_MACRO).  These are typically 20% faster
00056 * but may lead to problems near the poles.
00057 *
00058 *
00059 * cosd() - Cosine of an angle in degrees
00060 * --------------------------------------
00061 * cosd() returns the cosine of an angle given in degrees.
00062 *
00063 * Given:
00064 *   angle     double    [deg].
00065 *
00066 * Function return value:
00067 *             double    Cosine of the angle.
00068 *
00069 *
00070 * sind() - Sine of an angle in degrees
00071 * ------------------------------------
00072 * sind() returns the sine of an angle given in degrees.
00073 *
00074 * Given:
00075 *   angle     double    [deg].
00076 *
00077 * Function return value:
00078 *             double    Sine of the angle.
00079 *
00080 *
00081 * sincosd() - Sine and cosine of an angle in degrees
00082 * --------------------------------------------------
00083 * sincosd() returns the sine and cosine of an angle given in degrees.
00084 *
00085 * Given:
00086 *   angle     double    [deg].
00087 *
00088 * Returned:
00089 *   sin       *double   Sine of the angle.
00090 *
00091 *   cos       *double   Cosine of the angle.
00092 *
00093 * Function return value:
00094 *             void
00095 *
00096 *
00097 * tand() - Tangent of an angle in degrees
00098 * ---------------------------------------
00099 * tand() returns the tangent of an angle given in degrees.
00100 *
00101 * Given:
00102 *   angle     double    [deg].
00103 *
00104 * Function return value:
00105 *             double    Tangent of the angle.
00106 *
00107 *
00108 * acosd() - Inverse cosine, returning angle in degrees
00109 * ----------------------------------------------------
00110 * acosd() returns the inverse cosine in degrees.
00111 *
00112 * Given:
00113 *   x         double    in the range [-1,1].
00114 *
00115 * Function return value:
00116 *             double    Inverse cosine of x [deg].
00117 *
```

```
00118 *
00119 * asind() - Inverse sine, returning angle in degrees
00120 * ---------------------------------------------------
00121 * asind() returns the inverse sine in degrees.
00122 *
00123 * Given:
00124 *   y         double    in the range [-1,1].
00125 *
00126 * Function return value:
00127 *             double    Inverse sine of y [deg].
00128 *
00129 *
00130 * atand() - Inverse tangent, returning angle in degrees
00131 * -----------------------------------------------------
00132 * atand() returns the inverse tangent in degrees.
00133 *
00134 * Given:
00135 *   s         double
00136 *
00137 * Function return value:
00138 *             double    Inverse tangent of s [deg].
00139 *
00140 *
00141 * atan2d() - Polar angle of (x,y), in degrees
00142 * -------------------------------------------
00143 * atan2d() returns the polar angle, beta, in degrees, of polar coordinates
00144 * (rho,beta) corresponding to Cartesian coordinates (x,y).  It is equivalent
00145 * to the arg(x,y) function of WCS Paper II, though with transposed arguments.
00146 *
00147 * Given:
00148 *   y         double    Cartesian y-coordinate.
00149 *
00150 *   x         double    Cartesian x-coordinate.
00151 *
00152 * Function return value:
00153 *             double    Polar angle of (x,y) [deg].

6.37.1 Detailed Description

Routines in this suite deal with units specifications and conversions, as described in
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

The Flexible Image Transport System (FITS), a data format widely used in astronomy for data interchange and archive, is described in
"Definition of the Flexible Image Transport System (FITS), version 3.0",
Pence, W.D., Chiappetti, L., Page, C.G., Shaw, R.A., & Stobie, E. 2010,
A&A, 524, A42 - http://dx.doi.org/10.1051/0004-6361/201015362

See also http:
These routines perform basic units-related operations:

- wcsunitse(): given two unit specifications, derive the conversion from one to the other.
- wcsutrne(): translates certain commonly used but non-standard unit strings. It is intended to be called before wcsulexe() which only handles standard FITS units specifications.
- wcsulexe(): parses a standard FITS units specification of arbitrary complexity, deriving the conversion to canonical units.

6.37.2 Macro Definition Documentation

WCSUNITS_PLANE_ANGLE

```
#define WCSUNITS_PLANE_ANGLE 0
```

Array index for plane angle units type.

Array index for plane angle units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_SOLID_ANGLE

```
#define WCSUNITS_SOLID_ANGLE 1
```

Array index for solid angle units type.

Array index for solid angle units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_CHARGE

```
#define WCSUNITS_CHARGE 2
```

Array index for charge units type.

Array index for charge units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_MOLE

```
#define WCSUNITS_MOLE 3
```

Array index for mole units type.

Array index for mole ("gram molecular weight") units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_TEMPERATURE

```
#define WCSUNITS_TEMPERATURE 4
```

Array index for temperature units type.

Array index for temperature units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_LUMINTEN

```
#define WCSUNITS_LUMINTEN 5
```

Array index for luminous intensity units type.

Array index for luminous intensity units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_MASS

```
#define WCSUNITS_MASS 6
```

Array index for mass units type.

Array index for mass units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_LENGTH

```
#define WCSUNITS_LENGTH 7
```

Array index for length units type.

Array index for length units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_TIME

```
#define WCSUNITS_TIME 8
```

Array index for time units type.

Array index for time units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_BEAM

```
#define WCSUNITS_BEAM 9
```

Array index for beam units type.

Array index for beam units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_BIN

```
#define WCSUNITS_BIN 10
```

Array index for bin units type.

Array index for bin units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_BIT

```
#define WCSUNITS_BIT 11
```

Array index for bit units type.

Array index for bit units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_COUNT

```
#define WCSUNITS_COUNT 12
```

Array index for count units type.

Array index for count units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_MAGNITUDE

```
#define WCSUNITS_MAGNITUDE 13
```

Array index for stellar magnitude units type.

Array index for stellar magnitude units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_PIXEL

```
#define WCSUNITS_PIXEL 14
```

Array index for pixel units type.

Array index for pixel units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_SOLRATIO

```
#define WCSUNITS_SOLRATIO 15
```

Array index for solar mass ratio units type.

Array index for solar mass ratio units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_VOXEL

```
#define WCSUNITS_VOXEL 16
```

Array index for voxel units type.

Array index for voxel units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_NTYPE

```
#define WCSUNITS_NTYPE 17
```

Number of entries in the units array.

Number of entries in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

wcsunitse()

```
int wcsunitse (
            const char have[],
            const char want[],
            double * scale,
            double * offset,
            double * power,
            struct wcserr ** err )
```

FITS units specification conversion.

wcsunitse() derives the conversion from one system of units to another.

A deprecated form of this function, wcsunits(), lacks the wcserr** parameter.

Parameters

in	*have*	FITS units specification to convert from (null- terminated), with or without surrounding square brackets (for inline specifications); text following the closing bracket is ignored.
in	*want*	FITS units specification to convert to (null- terminated), with or without surrounding square brackets (for inline specifications); text following the closing bracket is ignored.

out	*scale,offset,power*	Convert units using
		`pow(scale*value + offset, power);`
		
		Normally *offset* is zero except for log() or ln() conversions, e.g. "log(MHz)" to "ln(Hz)". Likewise, *power* is normally unity except for exp() conversions, e.g. "exp(ms)" to "exp(/Hz)". Thus conversions ordinarily consist of
		`value *= scale;`

out	*err*	If enabled, for function return values $>$ 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 1-9: Status return from wcsulexe().
- 10: Non-conformant unit specifications.
- 11: Non-conformant functions.

scale is zeroed on return if an error occurs.

wcsutrne()

```
int wcsutrne (
              int ctrl,
              char unitstr[],
              struct wcserr ** err )
```

Translation of non-standard unit specifications.

wcsutrne() translates certain commonly used but non-standard unit strings, e.g. "DEG", "MHZ", "KELVIN", that are not recognized by wcsulexe(), refer to the notes below for a full list. Compounds are also recognized, e.g. "JY/BEAM" and "KM/SEC/SEC". Extraneous embedded blanks are removed.

A deprecated form of this function, wcsutrn(), lacks the wcserr$**$ parameter.

Parameters

in	*ctrl*	Although "S" is commonly used to represent seconds, its translation to "s" is potentially unsafe since the standard recognizes "S" formally as Siemens, however rarely that may be used. The same applies to "H" for hours (Henry), and "D" for days (Debye). This bit-flag controls what to do in such cases: • 1: Translate "S" to "s". • 2: Translate "H" to "h". • 4: Translate "D" to "d". Thus ctrl == 0 doesn't do any unsafe translations, whereas ctrl == 7 does all of them.
in,out	*unitstr*	Null-terminated character array containing the units specification to be translated. Inline units specifications in a FITS header keycomment are also handled. If the first non-blank character in unitstr is '[' then the unit string is delimited by its matching ']'. Blanks preceding '[' will be stripped off, but text following the closing bracket will be preserved without modification.
in,out	*err*	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- -1: No change was made, other than stripping blanks (not an error).
- 0: Success.
- 9: Internal parser error.
- 12: Potentially unsafe translation, whether applied or not (see notes).

Notes:

1. Translation of non-standard unit specifications: apart from leading and trailing blanks, a case-sensitive match is required for the aliases listed below, in particular the only recognized aliases with metric prefixes are "KM", "KHZ", "MHZ", and "GHZ". Potentially unsafe translations of "D", "H", and "S", shown in parentheses, are optional.

```
Unit       Recognized aliases
----       ------------------------------------------------------
Angstrom   Angstroms angstrom angstroms
arcmin     arcmins, ARCMIN, ARCMINS
arcsec     arcsecs, ARCSEC, ARCSECS
beam       BEAM
byte       Byte
d          day, days, (D), DAY, DAYS
deg        degree, degrees, Deg, Degree, Degrees, DEG, DEGREE,
           DEGREES
GHz        GHZ
h          hr, (H), HR
Hz         hz, HZ
kHz        KHZ
Jy         JY
K          kelvin, kelvins, Kelvin, Kelvins, KELVIN, KELVINS
km         KM
m          metre, meter, metres, meters, M, METRE, METER, METRES,
           METERS
min        MIN
MHz        MHZ
Ohm        ohm
Pa         pascal, pascals, Pascal, Pascals, PASCAL, PASCALS
pixel      pixels, PIXEL, PIXELS
```

```
rad         radian, radians, RAD, RADIAN, RADIANS
s           sec, second, seconds, (S), SEC, SECOND, SECONDS
V           volt, volts, Volt, Volts, VOLT, VOLTS
yr          year, years, YR, YEAR, YEARS
```

The aliases "angstrom", "ohm", and "Byte" for (Angstrom, Ohm, and byte) are recognized by wcsulexe() itself as an unofficial extension of the standard, but they are converted to the standard form here.

wcsulexe()

```
int wcsulexe (
              const char unitstr[],
              int * func,
              double * scale,
              double units[WCSUNITS_NTYPE],
              struct wcserr ** err )
```

FITS units specification parser.

wcsulexe() parses a standard FITS units specification of arbitrary complexity, deriving the scale factor required to convert to canonical units - basically SI with degrees and "dimensionless" additions such as byte, pixel and count.

A deprecated form of this function, wcsulex(), lacks the wcserr** parameter.

Parameters

in	*unitstr*	Null-terminated character array containing the units specification, with or without surrounding square brackets (for inline specifications); text following the closing bracket is ignored.
out	*func*	Special function type, see note 4: • 0: None • 1: log() ...base 10 • 2: ln() ...base e • 3: exp()
out	*scale*	Scale factor for the unit specification; multiply a value expressed in the given units by this factor to convert it to canonical units.
out	*units*	A units specification is decomposed into powers of 16 fundamental unit types: angle, mass, length, time, count, pixel, etc. Preprocessor macro WCSUNITS_NTYPE is defined to dimension this vector, and others such WCSUNITS_PLANE_ANGLE, WCSUNITS_LENGTH, etc. to access its elements. Corresponding character strings, wcsunits_types[] and wcsunits_units[], are predefined to describe each quantity and its canonical units.
out	*err*	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 1: Invalid numeric multiplier.
- 2: Dangling binary operator.

- 3: Invalid symbol in INITIAL context.
- 4: Function in invalid context.
- 5: Invalid symbol in EXPON context.
- 6: Unbalanced bracket.
- 7: Unbalanced parenthesis.
- 8: Consecutive binary operators.
- 9: Internal parser error.

scale and units[] are zeroed on return if an error occurs.

Notes:

1. **wcsulexe**() is permissive in accepting whitespace in all contexts in a units specification where it does not create ambiguity (e.g. not between a metric prefix and a basic unit string), including in strings like "log (m $**$ 2)" which is formally disallowed.
2. Supported extensions:
   - "angstrom" (OGIP usage) is allowed in addition to "Angstrom".
   - "ohm" (OGIP usage) is allowed in addition to "Ohm".
   - "Byte" (common usage) is allowed in addition to "byte".
3. Table 6 of WCS Paper I lists eleven units for which metric prefixes are allowed. However, in this implementation only prefixes greater than unity are allowed for "a" (annum), "yr" (year), "pc" (parsec), "bit", and "byte", and only prefixes less than unity are allowed for "mag" (stellar magnitude).

   Metric prefix "P" (peta) is specifically forbidden for "a" (annum) to avoid confusion with "Pa" (Pascal, not peta-annum). Note that metric prefixes are specifically disallowed for "h" (hour) and "d" (day) so that "ph" (photons) cannot be interpreted as pico-hours, nor "cd" (candela) as centi-days.
4. Function types log(), ln() and exp() may only occur at the start of the units specification. The scale and units[] returned for these refers to the string inside the function "argument", e.g. to "MHz" in log(MHz) for which a scale of 10^6 will be returned.

wcsunits()

```
int wcsunits (
             const char have[],
             const char want[],
             double * scale,
             double * offset,
             double * power )
```

wcsutrn()

```
int wcsutrn (
             int ctrl,
             char unitstr[] )
```

wcsulex()

```
int wcsulex (
             const char unitstr[],
             int * func,
             double * scale,
             double units[WCSUNITS_NTYPE] )
```

6.37.5 Variable Documentation

wcsunits_errmsg

```
const char * wcsunits_errmsg[]  [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

wcsunits_types

```
const char * wcsunits_types[]  [extern]
```

Names of physical quantities.

Names for physical quantities to match the units vector returned by **wcsulexe**():

- 0: plane angle
- 1: solid angle
- 2: charge
- 3: mole
- 4: temperature
- 5: luminous intensity
- 6: mass
- 7: length
- 8: time
- 9: beam
- 10: bin
- 11: bit
- 12: count
- 13: stellar magnitude
- 14: pixel
- 15: solar ratio
- 16: voxel

wcsunits_units

```
const char * wcsunits_units[]  [extern]
```

Names of units.

Names for the units (SI) to match the units vector returned by **wcsulexe**():

- 0: degree
- 1: steradian
- 2: Coulomb
- 3: mole
- 4: Kelvin
- 5: candela
- 6: kilogram
- 7: metre
- 8: second

The remainder are dimensionless.

00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wcsunits routines
00031 * --------------------------------
00032 * Routines in this suite deal with units specifications and conversions, as
00033 * described in
00034 *
00035 =   "Representations of world coordinates in FITS",
00036 =   Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00037 *
00038 * The Flexible Image Transport System (FITS), a data format widely used in
00039 * astronomy for data interchange and archive, is described in
00040 *
```

```
00041 =   "Definition of the Flexible Image Transport System (FITS), version 3.0",
00042 =   Pence, W.D., Chiappetti, L., Page, C.G., Shaw, R.A., & Stobie, E. 2010,
00043 =   A&A, 524, A42 - http://dx.doi.org/10.1051/0004-6361/201015362
00044 *
00045 * See also http://fits.gsfc.nasa.gov
00046 *
00047 * These routines perform basic units-related operations:
00048 *
00049 *   - wcsunitse(): given two unit specifications, derive the conversion from
00050 *     one to the other.
00051 *
00052 *   - wcsutrne(): translates certain commonly used but non-standard unit
00053 *     strings.  It is intended to be called before wcsulexe() which only
00054 *     handles standard FITS units specifications.
00055 *
00056 *   - wcsulexe(): parses a standard FITS units specification of arbitrary
00057 *     complexity, deriving the conversion to canonical units.
00058 *
00059 *
00060 * wcsunitse() - FITS units specification conversion
00061 * ------------------------------------------------
00062 * wcsunitse() derives the conversion from one system of units to another.
00063 *
00064 * A deprecated form of this function, wcsunits(), lacks the wcserr**
00065 * parameter.
00066 *
00067 * Given:
00068 *   have      const char []
00069 *                       FITS units specification to convert from (null-
00070 *                       terminated), with or without surrounding square
00071 *                       brackets (for inline specifications); text following
00072 *                       the closing bracket is ignored.
00073 *
00074 *   want      const char []
00075 *                       FITS units specification to convert to (null-
00076 *                       terminated), with or without surrounding square
00077 *                       brackets (for inline specifications); text following
00078 *                       the closing bracket is ignored.
00079 *
00080 * Returned:
00081 *   scale,
00082 *   offset,
00083 *   power     double*   Convert units using
00084 *
00085 =                         pow(scale*value + offset, power);
00086 *
00087 *                       Normally offset is zero except for log() or ln()
00088 *                       conversions, e.g. "log(MHz)" to "ln(Hz)".  Likewise,
00089 *                       power is normally unity except for exp() conversions,
00090 *                       e.g. "exp(ms)" to "exp(/Hz)".  Thus conversions
00091 *                       ordinarily consist of
00092 *
00093 =                         value *= scale;
00094 *
00095 *   err       struct wcserr **
00096 *                       If enabled, for function return values > 1, this
00097 *                       struct will contain a detailed error message, see
00098 *                       wcserr_enable().  May be NULL if an error message is
00099 *                       not desired.  Otherwise, the user is responsible for
00100 *                       deleting the memory allocated for the wcserr struct.
00101 *
00102 * Function return value:
00103 *             int       Status return value:
00104 *                         0: Success.
00105 *                       1-9: Status return from wcsulexe().
00106 *                        10: Non-conformant unit specifications.
00107 *                        11: Non-conformant functions.
00108 *
00109 *                       scale is zeroed on return if an error occurs.
00110 *
00111 *
00112 * wcsutrne() - Translation of non-standard unit specifications
00113 * ------------------------------------------------------------
00114 * wcsutrne() translates certain commonly used but non-standard unit strings,
00115 * e.g. "DEG", "MHZ", "KELVIN", that are not recognized by wcsulexe(), refer to
00116 * the notes below for a full list.  Compounds are also recognized, e.g.
00117 * "JY/BEAM" and "KM/SEC/SEC".  Extraneous embedded blanks are removed.
00118 *
00119 * A deprecated form of this function, wcsutrn(), lacks the wcserr** parameter.
00120 *
00121 * Given:
00122 *   ctrl      int       Although "S" is commonly used to represent seconds,
00123 *                       its translation to "s" is potentially unsafe since the
00124 *                       standard recognizes "S" formally as Siemens, however
00125 *                       rarely that may be used.  The same applies to "H" for
00126 *                       hours (Henry), and "D" for days (Debye).  This
00127 *                       bit-flag controls what to do in such cases:
```

```
00128 *                         1: Translate "S" to "s".
00129 *                         2: Translate "H" to "h".
00130 *                         4: Translate "D" to "d".
00131 *                       Thus ctrl == 0 doesn't do any unsafe translations,
00132 *                       whereas ctrl == 7 does all of them.
00133 *
00134 * Given and returned:
00135 *   unitstr   char []   Null-terminated character array containing the units
00136 *                       specification to be translated.
00137 *
00138 *                       Inline units specifications in a FITS header
00139 *                       keycomment are also handled.  If the first non-blank
00140 *                       character in unitstr is '[' then the unit string is
00141 *                       delimited by its matching ']'.  Blanks preceding '['
00142 *                       will be stripped off, but text following the closing
00143 *                       bracket will be preserved without modification.
00144 *
00145 *   err       struct wcserr **
00146 *                       If enabled, for function return values > 1, this
00147 *                       struct will contain a detailed error message, see
00148 *                       wcserr_enable().  May be NULL if an error message is
00149 *                       not desired.  Otherwise, the user is responsible for
00150 *                       deleting the memory allocated for the wcserr struct.
00151 *
00152 * Function return value:
00153 *             int       Status return value:
00154 *                        -1: No change was made, other than stripping blanks
00155 *                            (not an error).
00156 *                         0: Success.
00157 *                         9: Internal parser error.
00158 *                        12: Potentially unsafe translation, whether applied
00159 *                            or not (see notes).
00160 *
00161 * Notes:
00162 *   1: Translation of non-standard unit specifications: apart from leading and
00163 *      trailing blanks, a case-sensitive match is required for the aliases
00164 *      listed below, in particular the only recognized aliases with metric
00165 *      prefixes are "KM", "KHZ", "MHZ", and "GHZ".  Potentially unsafe
00166 *      translations of "D", "H", and "S", shown in parentheses, are optional.
00167 *
00168 =        Unit       Recognized aliases

00196 *
00197 *      The aliases "angstrom", "ohm", and "Byte" for (Angstrom, Ohm, and byte)
00198 *      are recognized by wcsulexe() itself as an unofficial extension of the
00199 *      standard, but they are converted to the standard form here.
00200 *
00201 *
00202 * wcsulexe() - FITS units specification parser
00203 * --------------------------------------------
00204 * wcsulexe() parses a standard FITS units specification of arbitrary
00205 * complexity, deriving the scale factor required to convert to canonical
00206 * units - basically SI with degrees and "dimensionless" additions such as
00207 * byte, pixel and count.
00208 *
00209 * A deprecated form of this function, wcsulex(), lacks the wcserr** parameter.
00210 *
00211 * Given:
00212 *   unitstr   const char []
00213 *                       Null-terminated character array containing the units
00214 *                       specification, with or without surrounding square
```

```
00215 *                      brackets (for inline specifications); text following
00216 *                      the closing bracket is ignored.
00217 *
00218 * Returned:
00219 *   func      int*      Special function type, see note 4:
00220 *                         0: None
00221 *                         1: log()  ...base 10
00222 *                         2: ln()   ...base e
00223 *                         3: exp()
00224 *
00225 *   scale     double*   Scale factor for the unit specification; multiply a
00226 *                      value expressed in the given units by this factor to
00227 *                      convert it to canonical units.
00228 *
00229 *   units     double[WCSUNITS_NTYPE]
00230 *                      A units specification is decomposed into powers of 16
00231 *                      fundamental unit types: angle, mass, length, time,
00232 *                      count, pixel, etc.  Preprocessor macro WCSUNITS_NTYPE
00233 *                      is defined to dimension this vector, and others such
00234 *                      WCSUNITS_PLANE_ANGLE, WCSUNITS_LENGTH, etc. to access
00235 *                      its elements.
00236 *
00237 *                      Corresponding character strings, wcsunits_types[] and
00238 *                      wcsunits_units[], are predefined to describe each
00239 *                      quantity and its canonical units.
00240 *
00241 *   err       struct wcserr **
00242 *                      If enabled, for function return values > 1, this
00243 *                      struct will contain a detailed error message, see
00244 *                      wcserr_enable().  May be NULL if an error message is
00245 *                      not desired.  Otherwise, the user is responsible for
00246 *                      deleting the memory allocated for the wcserr struct.
00247 *
00248 * Function return value:
00249 *             int       Status return value:
00250 *                         0: Success.
00251 *                         1: Invalid numeric multiplier.
00252 *                         2: Dangling binary operator.
00253 *                         3: Invalid symbol in INITIAL context.
00254 *                         4: Function in invalid context.
00255 *                         5: Invalid symbol in EXPON context.
00256 *                         6: Unbalanced bracket.
00257 *                         7: Unbalanced parenthesis.
00258 *                         8: Consecutive binary operators.
00259 *                         9: Internal parser error.
00260 *
00261 *                      scale and units[] are zeroed on return if an error
00262 *                      occurs.
00263 *
00264 * Notes:
00265 *   1: wcsulexe() is permissive in accepting whitespace in all contexts in a
00266 *      units specification where it does not create ambiguity (e.g. not
00267 *      between a metric prefix and a basic unit string), including in strings
00268 *      like "log (m ** 2)" which is formally disallowed.
00269 *
00270 *   2: Supported extensions:
00271 *      - "angstrom" (OGIP usage) is allowed in addition to "Angstrom".
00272 *      - "ohm"      (OGIP usage) is allowed in addition to "Ohm".
00273 *      - "Byte"   (common usage) is allowed in addition to "byte".
00274 *
00275 *   3: Table 6 of WCS Paper I lists eleven units for which metric prefixes are
00276 *      allowed.  However, in this implementation only prefixes greater than
00277 *      unity are allowed for "a" (annum), "yr" (year), "pc" (parsec), "bit",
00278 *      and "byte", and only prefixes less than unity are allowed for "mag"
00279 *      (stellar magnitude).
00280 *
00281 *      Metric prefix "P" (peta) is specifically forbidden for "a" (annum) to
00282 *      avoid confusion with "Pa" (Pascal, not peta-annum).  Note that metric
00283 *      prefixes are specifically disallowed for "h" (hour) and "d" (day) so
00284 *      that "ph" (photons) cannot be interpreted as pico-hours, nor "cd"
00285 *      (candela) as centi-days.
00286 *
00287 *   4: Function types log(), ln() and exp() may only occur at the start of the
00288 *      units specification.  The scale and units[] returned for these refers
00289 *      to the string inside the function "argument", e.g. to "MHz" in log(MHz)
00290 *      for which a scale of 1e6 will be returned.
00291 *
00292 *
00293 * Global variable: const char *wcsunits_errmsg[] - Status return messages
00294 * ----------------------------------------------------------------------
00295 * Error messages to match the status value returned from each function.
00296 *
00297 *
00298 * Global variable: const char *wcsunits_types[] - Names of physical quantities
00299 * ----------------------------------------------------------------------------
00300 * Names for physical quantities to match the units vector returned by
00301 * wcsulexe():
```

```
00302 *   -  0: plane angle
00303 *   -  1: solid angle
00304 *   -  2: charge
00305 *   -  3: mole
00306 *   -  4: temperature
00307 *   -  5: luminous intensity
00308 *   -  6: mass
00309 *   -  7: length
00310 *   -  8: time
00311 *   -  9: beam
00312 *   - 10: bin
00313 *   - 11: bit
00314 *   - 12: count
00315 *   - 13: stellar magnitude

6.39 wcsutil.h File Reference

Functions

- void wcsdealloc (void *ptr)

  free memory allocated by WCSLIB functions.
- void wcsutil_strcvt (int n, char c, int nt, const char src[ ], char dst[ ])

  Copy character string with padding.
- void wcsutil_blank_fill (int n, char c[ ])

  Fill a character string with blanks.
- void wcsutil_null_fill (int n, char c[ ])

  Fill a character string with NULLs.
- int wcsutil_all_ival (int nelem, int ival, const int iarr[ ])

  Test if all elements an int array have a given value.
- int wcsutil_all_dval (int nelem, double dval, const double darr[ ])

  Test if all elements a double array have a given value.
- int wcsutil_all_sval (int nelem, const char *sval, const char(*sarr)[72])

  Test if all elements a string array have a given value.
- int wcsutil_allEq (int nvec, int nelem, const double *first)

  Test for equality of a particular vector element.
- int wcsutil_dblEq (int nelem, double tol, const double *arr1, const double *arr2)

  Test for equality of two arrays of type double.
- int wcsutil_intEq (int nelem, const int *arr1, const int *arr2)

  Test for equality of two arrays of type int.
- int wcsutil_strEq (int nelem, char(*arr1)[72], char(*arr2)[72])

  Test for equality of two string arrays.
- void wcsutil_setAll (int nvec, int nelem, double *first)

  Set a particular vector element.
- void wcsutil_setAli (int nvec, int nelem, int *first)

  Set a particular vector element.
- void wcsutil_setBit (int nelem, const int *sel, int bits, int *array)

  Set bits in selected elements of an array.
- char * wcsutil_fptr2str (void(*fptr)(void), char hext[19])

  Translate pointer-to-function to string.
- void wcsutil_double2str (char *buf, const char *format, double value)

  Translate double to string ignoring the locale.
- int wcsutil_str2double (const char *buf, double *value)

  Translate string to a double, ignoring the locale.
- int wcsutil_str2double2 (const char *buf, double *value)

  Translate string to doubles, ignoring the locale.

6.39.1 Detailed Description

Simple utility functions. With the exception of wcsdealloc(), these functions are intended for **internal use only** by WCSLIB.

The internal-use functions are documented here solely as an aid to understanding the code. They are not intended for external use - the API may change without notice!

6.39.2 Function Documentation

wcsdealloc()

```
void wcsdealloc (
             void * ptr )
```

free memory allocated by WCSLIB functions.

wcsdealloc() invokes the free() system routine to free memory. Specifically, it is intended to free memory allocated (using calloc()) by certain WCSLIB functions (e.g. wcshdo(), wcsfixi(), fitshdr()), which it is the user's responsibility to deallocate.

In certain situations, for example multithreading, it may be important that this be done within the WCSLIB sharable library's runtime environment.

PLEASE NOTE: wcsdealloc() must not be used in place of the destructors for particular structs, such as wcsfree(), celfree(), etc.

Parameters

in,out	*ptr*	Address of the allocated memory.

Returns

wcsutil_strcvt()

```
void wcsutil_strcvt (
             int n,
             char c,
             int nt,
             const char src[],
             char dst[] )
```

Copy character string with padding.

INTERNAL USE ONLY.

wcsutil_strcvt() copies one character string to another up to the specified maximum number of characters.

If the given string is null-terminated, then the NULL character copied to the returned string, and all characters following it up to the specified maximum, are replaced with the specified substitute character, either blank or NULL.

If the source string is not null-terminated and the substitute character is blank, then copy the maximum number of characters and do nothing further. However, if the substitute character is NULL, then the last character and all consecutive blank characters preceding it will be replaced with NULLs.

Used by the Fortran wrapper functions in translating C strings into Fortran CHARACTER variables and vice versa.

Parameters

in	*n*	Maximum number of characters to copy.
in	*c*	Substitute character, either NULL or blank (anything other than NULL).
in	*nt*	If true, then dst is of length n+1, with the last character always set to NULL.
in	*src*	Character string to be copied. If null-terminated, then need not be of length n, otherwise it must be.
out	*dst*	Destination character string, which must be long enough to hold n characters. Note that this string will not be null-terminated if the substitute character is blank.

Returns

wcsutil_blank_fill()

```
void wcsutil_blank_fill (
             int n,
             char c[] )
```

Fill a character string with blanks.

INTERNAL USE ONLY.

wcsutil_blank_fill() pads a character sub-string with blanks starting with the terminating NULL character (if any).

Parameters

in	*n*	Length of the sub-string.
in,out	*c*	The character sub-string, which will not be null-terminated on return.

Returns

wcsutil_null_fill()

```
void wcsutil_null_fill (
             int n,
             char c[] )
```

Fill a character string with NULLs.

INTERNAL USE ONLY.

wcsutil_null_fill() strips trailing blanks from a string (or sub-string) and propagates the terminating NULL character (if any) to the end of the string.

If the string is not null-terminated, then the last character and all consecutive blank characters preceding it will be replaced with NULLs.

Mainly used in the C library to strip trailing blanks from FITS keyvalues. Also used to make character strings intelligible in the GNU debugger, which prints the rubbish following the terminating NULL character, thereby obscuring the valid part of the string.

Parameters

in	*n*	Number of characters.
in,out	*c*	The character (sub-)string.

Returns

wcsutil_all_ival()

```
int wcsutil_all_ival (
            int nelem,
            int ival,
            const int iarr[] )
```

Test if all elements an int array have a given value.

INTERNAL USE ONLY.

wcsutil_all_ival() tests whether all elements of an array of type int all have the specified value.

Parameters

in	*nelem*	The length of the array.
in	*ival*	Value to be tested.
in	*iarr*	Pointer to the first element of the array.

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_all_dval()

```
int wcsutil_all_dval (
            int nelem,
            double dval,
            const double darr[] )
```

Test if all elements a double array have a given value.

INTERNAL USE ONLY.

wcsutil_all_dval() tests whether all elements of an array of type double all have the specified value.

Parameters

in	*nelem*	The length of the array.
in	*dval*	Value to be tested.
in	*darr*	Pointer to the first element of the array.

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_all_sval()

```
int wcsutil_all_sval (
            int nelem,
            const char * sval,
            const char(*) sarr[72] )
```

Test if all elements a string array have a given value.

INTERNAL USE ONLY.

wcsutil_all_sval() tests whether the elements of an array of type char (∗)[72] all have the specified value.

Parameters

in	*nelem*	The length of the array.
in	*sval*	String to be tested.
in	*sarr*	Pointer to the first element of the array.

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_allEq()

```
int wcsutil_allEq (
            int nvec,
            int nelem,
            const double * first )
```

Test for equality of a particular vector element.

INTERNAL USE ONLY.

wcsutil_allEq() tests for equality of a particular element in a set of vectors.

Parameters

in	*nvec*	The number of vectors.
in	*nelem*	The length of each vector.

in	*first*	Pointer to the first element to test in the array. The elements tested for equality are
		`*first == *(first + nelem)  == *(first + nelem*2)`
		`:`
		`== *(first + nelem*(nvec-1));`
		
		The array might be dimensioned as
		`double v[nvec][nelem];`

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_dblEq()

```
int wcsutil_dblEq (
            int nelem,
            double tol,
            const double * arr1,
            const double * arr2 )
```

Test for equality of two arrays of type double.

INTERNAL USE ONLY.

wcsutil_dblEq() tests for equality of two double-precision arrays.

Parameters

in	*nelem*	The number of elements in each array.
in	*tol*	Tolerance for comparison of the floating-point values. For example, for tol == 1e-6, all floating-point values in the arrays must be equal to the first 6 decimal places. A value of 0 implies exact equality.
in	*arr1*	The first array.
in	*arr2*	The second array

Returns

Status return value:

- 0: Not equal.
- 1: Equal.

wcsutil_intEq()

```
int wcsutil_intEq (
            int nelem,
```

```
            const int * arr1,
            const int * arr2 )
```

Test for equality of two arrays of type int.

INTERNAL USE ONLY.

wcsutil_intEq() tests for equality of two int arrays.

Parameters

in	*nelem*	The number of elements in each array.
in	*arr1*	The first array.
in	*arr2*	The second array

Returns

Status return value:

- 0: Not equal.
- 1: Equal.

wcsutil_strEq()

```
int wcsutil_strEq (
            int nelem,
            char(*) arr1[72],
            char(*) arr2[72] )
```

Test for equality of two string arrays.

INTERNAL USE ONLY.

wcsutil_strEq() tests for equality of two string arrays.

Parameters

in	*nelem*	The number of elements in each array.
in	*arr1*	The first array.
in	*arr2*	The second array

Returns

Status return value:

- 0: Not equal.
- 1: Equal.

wcsutil_setAll()

```
void wcsutil_setAll (
            int nvec,
```

```
            int nelem,
            double * first )
```

Set a particular vector element.

INTERNAL USE ONLY.

wcsutil_setAll() sets the value of a particular element in a set of vectors of type double.

Parameters

in	*nvec*	The number of vectors.
in	*nelem*	The length of each vector.

in,out	*first*	Pointer to the first element in the array, the value of which is used to set the others
		`*(first + nelem) = *first;  *(first + nelem*2) = *first;`
		`:`
		`*(first + nelem*(nvec-1)) = *first;`
		
		The array might be dimensioned as
		`double v[nvec][nelem];`

Returns

wcsutil_setAli()

```
void wcsutil_setAli (
            int nvec,
            int nelem,
            int * first )
```

Set a particular vector element.

INTERNAL USE ONLY.

wcsutil_setAli() sets the value of a particular element in a set of vectors of type int.

Parameters

in	*nvec*	The number of vectors.
in	*nelem*	The length of each vector.

in,out	*first*	Pointer to the first element in the array, the value of which is used to set the others
		`*(first + nelem) = *first;  *(first + nelem*2) = *first;`
		`:`
		`*(first + nelem*(nvec-1)) = *first;`
		
		The array might be dimensioned as
		`int v[nvec][nelem];`

Returns

wcsutil_setBit()

```
void wcsutil_setBit (
             int nelem,
             const int * sel,
             int bits,
             int * array )
```

Set bits in selected elements of an array.

INTERNAL USE ONLY.

wcsutil_setBit() sets bits in selected elements of an array.

Parameters

in	*nelem*	Number of elements in the array.
in	*sel*	Address of a selection array of length nelem. May be specified as the null pointer in which case all elements are selected.
in	*bits*	Bit mask.
in,out	*array*	Address of the array of length nelem.

Returns

wcsutil_fptr2str()

```
char * wcsutil_fptr2str (
             void(*)(void) fptr,
             char hext[19] )
```

Translate pointer-to-function to string.

INTERNAL USE ONLY.

wcsutil_fptr2str() translates a pointer-to-function to hexadecimal string representation for output. It is used by the various routines that print the contents of WCSLIB structs, noting that it is not strictly legal to type-pun a function pointer to void∗. See http://stackoverflow.com/questions/2741683/how-to-format-a-function-point

Parameters

in	*fptr*	
out	*hext*	Null-terminated string. Should be at least 19 bytes in size to accomodate a 64-bit address (16 bytes in hex), plus the leading "0x" and trailing '\0'.

Returns

The address of hext.

wcsutil_double2str()

```
void wcsutil_double2str (
             char * buf,
             const char * format,
             double value )
```

Translate double to string ignoring the locale.

INTERNAL USE ONLY.

wcsutil_double2str() converts a double to a string, but unlike `sprintf()` it ignores the locale and always uses a '.' as the decimal separator. Also, unless it includes an exponent, the formatted value will always have a fractional part, ".0" being appended if necessary.

Parameters

out	*buf*	The buffer to write the string into.
in	*format*	The formatting directive, such as "f". This may be any of the forms accepted by `sprintf()`, but should only include a formatting directive and nothing else. For "g" and "G" formats, unless it includes an exponent, the formatted value will always have a fractional part, ".0" being appended if necessary.
in	*value*	The value to convert to a string.

wcsutil_str2double()

```
int wcsutil_str2double (
             const char * buf,
             double * value )
```

Translate string to a double, ignoring the locale.

INTERNAL USE ONLY.

wcsutil_str2double() converts a string to a double, but unlike `sscanf()` it ignores the locale and always expects a '.' as the decimal separator.

Parameters

in	*buf*	The string containing the value
out	*value*	The double value parsed from the string.

wcsutil_str2double2()

```
int wcsutil_str2double2 (
             const char * buf,
             double * value )
```

Translate string to doubles, ignoring the locale.

INTERNAL USE ONLY.

wcsutil_str2double2() converts a string to a pair of doubles containing the integer and fractional parts. Unlike `sscanf()` it ignores the locale and always expects a '.' as the decimal separator.

Parameters

in	*buf*	The string containing the value
out	*value*	parts, parsed from the string.

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wcsutil routines
00031 * -------------------------------
00032 * Simple utility functions.  With the exception of wcsdealloc(), these
00033 * functions are intended for internal use only by WCSLIB.
00034 *
00035 * The internal-use functions are documented here solely as an aid to
00036 * understanding the code.  They are not intended for external use - the API
00037 * may change without notice!
00038 *
00039 *
00040 * wcsdealloc() - free memory allocated by WCSLIB functions
00041 * --------------------------------------------------------
00042 * wcsdealloc() invokes the free() system routine to free memory.
00043 * Specifically, it is intended to free memory allocated (using calloc()) by
00044 * certain WCSLIB functions (e.g. wcshdo(), wcsfixi(), fitshdr()), which it is
00045 * the user's responsibility to deallocate.
00046 *
00047 * In certain situations, for example multithreading, it may be important that
00048 * this be done within the WCSLIB sharable library's runtime environment.
00049 *
00050 * PLEASE NOTE: wcsdealloc() must not be used in place of the destructors for
00051 * particular structs, such as wcsfree(), celfree(), etc.
00052 *
00053 * Given and returned:
00054 *   ptr       void*     Address of the allocated memory.
00055 *
00056 * Function return value:
00057 *             void
00058 *
00059 *
00060 * wcsutil_strcvt() - Copy character string with padding
00061 * -----------------------------------------------------
00062 * INTERNAL USE ONLY.
00063 *
00064 * wcsutil_strcvt() copies one character string to another up to the specified
00065 * maximum number of characters.
00066 *
```

```
00067 * If the given string is null-terminated, then the NULL character copied to
00068 * the returned string, and all characters following it up to the specified
00069 * maximum, are replaced with the specified substitute character, either blank
00070 * or NULL.
00071 *
00072 * If the source string is not null-terminated and the substitute character is
00073 * blank, then copy the maximum number of characters and do nothing further.
00074 * However, if the substitute character is NULL, then the last character and
00075 * all consecutive blank characters preceding it will be replaced with NULLs.
00076 *
00077 * Used by the Fortran wrapper functions in translating C strings into Fortran
00078 * CHARACTER variables and vice versa.
00079 *
00080 * Given:
00081 *   n          int       Maximum number of characters to copy.
00082 *
00083 *   c          char      Substitute character, either NULL or blank (anything
00084 *                        other than NULL).
00085 *
00086 *   nt         int       If true, then dst is of length n+1, with the last
00087 *                        character always set to NULL.
00088 *
00089 *   src        char[]    Character string to be copied.  If null-terminated,
00090 *                        then need not be of length n, otherwise it must be.
00091 *
00092 * Returned:
00093 *   dst        char[]    Destination character string, which must be long
00094 *                        enough to hold n characters.  Note that this string
00095 *                        will not be null-terminated if the substitute
00096 *                        character is blank.
00097 *
00098 * Function return value:
00099 *             void
00100 *
00101 *
00102 * wcsutil_blank_fill() - Fill a character string with blanks
00103 * ---------------------------------------------------------
00104 * INTERNAL USE ONLY.
00105 *
00106 * wcsutil_blank_fill() pads a character sub-string with blanks starting with
00107 * the terminating NULL character (if any).
00108 *
00109 * Given:
00110 *   n          int       Length of the sub-string.
00111 *
00112 * Given and returned:
00113 *   c          char[]    The character sub-string, which will not be
00114 *                        null-terminated on return.
00115 *
00116 * Function return value:
00117 *             void
00118 *
00119 *
00120 * wcsutil_null_fill() - Fill a character string with NULLs
00121 * --------------------------------------------------------
00122 * INTERNAL USE ONLY.
00123 *
00124 * wcsutil_null_fill() strips trailing blanks from a string (or sub-string) and
00125 * propagates the terminating NULL character (if any) to the end of the string.
00126 *
00127 * If the string is not null-terminated, then the last character and all
00128 * consecutive blank characters preceding it will be replaced with NULLs.
00129 *
00130 * Mainly used in the C library to strip trailing blanks from FITS keyvalues.
00131 * Also used to make character strings intelligible in the GNU debugger, which
00132 * prints the rubbish following the terminating NULL character, thereby
00133 * obscuring the valid part of the string.
00134 *
00135 * Given:
00136 *   n          int       Number of characters.
00137 *
00138 * Given and returned:
00139 *   c          char[]    The character (sub-)string.
00140 *
00141 * Function return value:
00142 *             void
00143 *
00144 *
00145 * wcsutil_all_ival() - Test if all elements an int array have a given value
00146 * -------------------------------------------------------------------------
00147 * INTERNAL USE ONLY.
00148 *
00149 * wcsutil_all_ival() tests whether all elements of an array of type int all
00150 * have the specified value.
00151 *
00152 * Given:
00153 *   nelem      int       The length of the array.
```

```
00154 *
00155 *   ival      int       Value to be tested.
00156 *
00157 *   iarr      const int[]
00158 *                       Pointer to the first element of the array.
00159 *
00160 * Function return value:
00161 *             int       Status return value:
00162 *                         0: Not all equal.
00163 *                         1: All equal.
00164 *
00165 *
00166 * wcsutil_all_dval() - Test if all elements a double array have a given value
00167 * ---------------------------------------------------------------------------
00168 * INTERNAL USE ONLY.
00169 *
00170 * wcsutil_all_dval() tests whether all elements of an array of type double all
00171 * have the specified value.
00172 *
00173 * Given:
00174 *   nelem     int       The length of the array.
00175 *
00176 *   dval      int       Value to be tested.
00177 *
00178 *   darr      const double[]
00179 *                       Pointer to the first element of the array.
00180 *
00181 * Function return value:
00182 *             int       Status return value:
00183 *                         0: Not all equal.
00184 *                         1: All equal.
00185 *
00186 *
00187 * wcsutil_all_sval() - Test if all elements a string array have a given value
00188 * ---------------------------------------------------------------------------
00189 * INTERNAL USE ONLY.
00190 *
00191 * wcsutil_all_sval() tests whether the elements of an array of type
00192 * char (*)[72] all have the specified value.
00193 *
00194 * Given:
00195 *   nelem     int       The length of the array.
00196 *
00197 *   sval      const char *
00198 *                       String to be tested.
00199 *
00200 *   sarr      const char (*)[72]
00201 *                       Pointer to the first element of the array.
00202 *
00203 * Function return value:
00204 *             int       Status return value:
00205 *                         0: Not all equal.
00206 *                         1: All equal.
00207 *
00208 *
00209 * wcsutil_allEq() - Test for equality of a particular vector element
00210 * -----------------------------------------------------------------
00211 * INTERNAL USE ONLY.
00212 *
00213 * wcsutil_allEq() tests for equality of a particular element in a set of
00214 * vectors.
00215 *
00216 * Given:
00217 *   nvec      int       The number of vectors.
00218 *
00219 *   nelem     int       The length of each vector.
00220 *
00221 *   first     const double*
00222 *                       Pointer to the first element to test in the array.
00223 *                       The elements tested for equality are
00224 *
00225 =                         *first == *(first + nelem)
00226 =                                == *(first + nelem*2)
00227 =                                       :
00228 =                                == *(first + nelem*(nvec-1));
00229 *
00230 *                       The array might be dimensioned as
00231 *
00232 =                         double v[nvec][nelem];
00233 *
00234 * Function return value:
00235 *             int       Status return value:
00236 *                         0: Not all equal.
00237 *                         1: All equal.
00238 *
00239 *
00240 * wcsutil_dblEq() - Test for equality of two arrays of type double
```

```
00241 * ------------------------------------------------------------
00242 * INTERNAL USE ONLY.
00243 *
00244 * wcsutil_dblEq() tests for equality of two double-precision arrays.
00245 *
00246 * Given:
00247 *   nelem     int       The number of elements in each array.
00248 *
00249 *   tol       double    Tolerance for comparison of the floating-point values.
00250 *                       For example, for tol == 1e-6, all floating-point
00251 *                       values in the arrays must be equal to the first 6
00252 *                       decimal places.  A value of 0 implies exact equality.
00253 *
00254 *   arr1      const double*
00255 *                       The first array.
00256 *
00257 *   arr2      const double*
00258 *                       The second array
00259 *
00260 * Function return value:
00261 *             int       Status return value:
00262 *                         0: Not equal.
00263 *                         1: Equal.
00264 *
00265 *
00266 * wcsutil_intEq() - Test for equality of two arrays of type int
00267 * ------------------------------------------------------------
00268 * INTERNAL USE ONLY.
00269 *
00270 * wcsutil_intEq() tests for equality of two int arrays.
00271 *
00272 * Given:
00273 *   nelem     int       The number of elements in each array.
00274 *
00275 *   arr1      const int*
00276 *                       The first array.
00277 *
00278 *   arr2      const int*
00279 *                       The second array
00280 *
00281 * Function return value:
00282 *             int       Status return value:
00283 *                         0: Not equal.
00284 *                         1: Equal.
00285 *
00286 *
00287 * wcsutil_strEq() - Test for equality of two string arrays
00288 * -------------------------------------------------------
00289 * INTERNAL USE ONLY.
00290 *
00291 * wcsutil_strEq() tests for equality of two string arrays.
00292 *
00293 * Given:
00294 *   nelem     int       The number of elements in each array.
00295 *
00296 *   arr1      const char**
00297 *                       The first array.
00298 *
00299 *   arr2      const char**
00300 *                       The second array
00301 *
00302 * Function return value:
00303 *             int       Status return value:
00304 *                         0: Not equal.
00305 *                         1: Equal.
00306 *
00307 *
00308 * wcsutil_setAll() - Set a particular vector element
00309 * -------------------------------------------------
00310 * INTERNAL USE ONLY.
00311 *
00312 * wcsutil_setAll() sets the value of a particular element in a set of vectors
00313 * of type double.
00314 *
00315 * Given:
00316 *   nvec      int       The number of vectors.
00317 *
00318 *   nelem     int       The length of each vector.
00319 *
00320 * Given and returned:
00321 *   first     double*   Pointer to the first element in the array, the value
00322 *                       of which is used to set the others
00323 *
00324 =                         *(first + nelem) = *first;
00325 =                         *(first + nelem*2) = *first;
00326 =                                 :
00327 =                         *(first + nelem*(nvec-1)) = *first;
```

```
00328 *
00329 *                       The array might be dimensioned as
00330 *
00331 =                         double v[nvec][nelem];
00332 *
00333 * Function return value:
00334 *             void
00335 *
00336 *
00337 * wcsutil_setAli() - Set a particular vector element
00338 * ------------------------------------------------
00339 * INTERNAL USE ONLY.
00340 *
00341 * wcsutil_setAli() sets the value of a particular element in a set of vectors
00342 * of type int.
00343 *
00344 * Given:
00345 *   nvec      int       The number of vectors.
00346 *
00347 *   nelem     int       The length of each vector.
00348 *
00349 * Given and returned:
00350 *   first     int*      Pointer to the first element in the array, the value
00351 *                       of which is used to set the others
00352 *
00353 =                         *(first + nelem) = *first;
00354 =                         *(first + nelem*2) = *first;
00355 =                                 :
00356 =                         *(first + nelem*(nvec-1)) = *first;
00357 *
00358 *                       The array might be dimensioned as
00359 *
00360 =                         int v[nvec][nelem];
00361 *
00362 * Function return value:
00363 *             void
00364 *
00365 *
00366 * wcsutil_setBit() - Set bits in selected elements of an array
00367 * ------------------------------------------------------------
00368 * INTERNAL USE ONLY.
00369 *
00370 * wcsutil_setBit() sets bits in selected elements of an array.
00371 *
00372 * Given:
00373 *   nelem     int       Number of elements in the array.
00374 *
00375 *   sel       const int*
00376 *                       Address of a selection array of length nelem.  May
00377 *                       be specified as the null pointer in which case all
00378 *                       elements are selected.
00379 *
00380 *   bits      int       Bit mask.
00381 *
00382 * Given and returned:
00383 *   array     int*      Address of the array of length nelem.
00384 *
00385 * Function return value:
00386 *             void
00387 *
00388 *
00389 * wcsutil_fptr2str() - Translate pointer-to-function to string
00390 * ------------------------------------------------------------
00391 * INTERNAL USE ONLY.
00392 *
00393 * wcsutil_fptr2str() translates a pointer-to-function to hexadecimal string
00394 * representation for output.  It is used by the various routines that print
00395 * the contents of WCSLIB structs, noting that it is not strictly legal to
00396 * type-pun a function pointer to void*.  See
00397 * http://stackoverflow.com/questions/2741683/how-to-format-a-function-pointer
00398 *
00399 * Given:
00400 *   fptr      void(*)() Pointer to function.
00401 *
00402 * Returned:
00403 *   hext      char[19]  Null-terminated string.  Should be at least 19 bytes
00404 *                       in size to accomodate a 64-bit address (16 bytes in
00405 *                       hex), plus the leading "0x" and trailing '\0'.
00406 *
00407 * Function return value:
00408 *             char *    The address of hext.
00409 *
00410 *
00411 * wcsutil_double2str() - Translate double to string ignoring the locale
00412 * ---------------------------------------------------------------------
00413 * INTERNAL USE ONLY.
00414 *
```

```
00415 * wcsutil_double2str() converts a double to a string, but unlike sprintf() it
00416 * ignores the locale and always uses a '.' as the decimal separator.  Also,
00417 * unless it includes an exponent, the formatted value will always have a
00418 * fractional part, ".0" being appended if necessary.
00419 *
00420 * Returned:
00421 *   buf       char *    The buffer to write the string into.
00422 *
00423 * Given:
00424 *   format    char *    The formatting directive, such as "%f".  This
00425 *                       may be any of the forms accepted by sprintf(), but
00426 *                       should only include a formatting directive and
00427 *                       nothing else.  For "%g" and "%G" formats, unless it
00428 *                       includes an exponent, the formatted value will always
00429 *                       have a fractional part, ".0" being appended if
00430 *                       necessary.
00431 *
00432 *   value     double    The value to convert to a string.
00433 *
00434 *
00435 * wcsutil_str2double() - Translate string to a double, ignoring the locale
00436 * ------------------------------------------------------------------------
00437 * INTERNAL USE ONLY.
00438 *
00439 * wcsutil_str2double() converts a string to a double, but unlike sscanf() it
00440 * ignores the locale and always expects a '.' as the decimal separator.
00441 *
00442 * Given:
00443 *   buf       char *    The string containing the value
00444 *
00445 * Returned:
00446 *   value     double *  The double value parsed from the string.
00447 *
00448 *
00449 * wcsutil_str2double2() - Translate string to doubles, ignoring the locale
00450 * ------------------------------------------------------------------------
00451 * INTERNAL USE ONLY.
00452 *
00453 * wcsutil_str2double2() converts a string to a pair of doubles containing the
00454 * integer and fractional parts.  Unlike sscanf() it ignores the locale and
00455 * always expects a '.' as the decimal separator.
00456 *
00457 * Given:
00458 *   buf       char *    The string containing the value
00459 *
00460 * Returned:
00461 *   value     double[2] The double value, split into integer and fractional
00462 *                       parts, parsed from the string.
00463 *

Data Structures

- struct wtbarr

  Extraction of coordinate lookup tables from BINTABLE.

6.41.1 Detailed Description

The wtbarr struct is used by wcstab() in extracting coordinate lookup tables from a binary table extension (BINTABLE) and copying them into the tabprm structs stored in wcsprm.

6.42 wtbarr.h

00023 *============================================================================
00024 *
00025 * WCSLIB 8.2 - C routines that implement the FITS World Coordinate System
00026 * (WCS) standard.  Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wtbarr struct
00031 * ----------------------------
00032 * The wtbarr struct is used by wcstab() in extracting coordinate lookup tables
00033 * from a binary table extension (BINTABLE) and copying them into the tabprm
00034 * structs stored in wcsprm.
00035 *
00036 *
00037 * wtbarr struct - Extraction of coordinate lookup tables from BINTABLE
00038 * --------------------------------------------------------------------
00039 * Function wcstab(), which is invoked automatically by wcspih(), sets up an
00040 * array of wtbarr structs to assist in extracting coordinate lookup tables
00041 * from a binary table extension (BINTABLE) and copying them into the tabprm
00042 * structs stored in wcsprm.  Refer to the usage notes for wcspih() and
00043 * wcstab() in wcshdr.h, and also the prologue to tab.h.
00044 *
00045 * For C++ usage, because of a name space conflict with the wtbarr typedef
00046 * defined in CFITSIO header fitsio.h, the wtbarr struct is renamed to wtbarr_s
00047 * by preprocessor macro substitution with scope limited to wtbarr.h itself,
00048 * and similarly in wcs.h.
00049 *
00050 *   int i
00051 *     (Given) Image axis number.
00052 *
00053 *   int m
00054 *     (Given) wcstab array axis number for index vectors.
00055 *
00056 *   int kind
00057 *     (Given) Character identifying the wcstab array type:
00058 *       - c: coordinate array,
```

```
00059 *       - i: index vector.
00060 *
00061 *   char extnam[72]
00062 *     (Given) EXTNAME identifying the binary table extension.
00063 *
00064 *   int extver
00065 *     (Given) EXTVER identifying the binary table extension.
00066 *
00067 *   int extlev
00068 *     (Given) EXTLEV identifying the binary table extension.
00069 *
00070 *   char ttype[72]
00071 *     (Given) TTYPEn identifying the column of the binary table that contains
00072 *     the wcstab array.
00073 *
00074 *   long row
00075 *     (Given) Table row number.
00076 *
00077 *   int ndim
00078 *     (Given) Expected dimensionality of the wcstab array.
00079 *
00080 *   int *dimlen
00081 *     (Given) Address of the first element of an array of int of length ndim
00082 *     into which the wcstab array axis lengths are to be written.
00083 *
00084 *   double **arrayp
00085 *     (Given) Pointer to an array of double which is to be allocated by the
00086 *     user and into which the wcstab array is to be written.
00087 *
00088 *===========================================================================*/

00058 #include "wtbarr.h"
00059
00060 #endif // WCSLIB_WCSLIB
03603   wcserr_enable(1);
03604   wcsprintf_set(stderr);
03605
03606   ...
03607
03608   if (wcsset(&wcs) {
03609     wcsperr(&wcs);
03610     return wcs.err->status;
03611   }
03612 @endverbatim
03613 In this example, if an error was generated in one of the prjset() functions,
03614 wcsperr() would print an error traceback starting with wcsset(), then
03615 celset(), and finally the particular projection-setting function that
03616 generated the error.  For each of them it would print the status return value,
03617 function name, source file, line number, and an error message which may be
03618 more specific and informative than the general error messages reported in the
03619 first example.  For example, in response to a deliberately generated error,
03620 the @c twcs test program, which tests wcserr among other things, produces a
03621 traceback similar to this:
03622 @verbatim
03623 ERROR 5 in wcsset() at line 1564 of file wcs.c:
03624   Invalid parameter value.
03625 ERROR 2 in celset() at line 196 of file cel.c:
03626   Invalid projection parameters.
03627 ERROR 2 in bonset() at line 5727 of file prj.c:
03628   Invalid parameters for Bonne's projection.
03629 @endverbatim
03630
03631 Each of the @ref structs "structs" in @ref overview "WCSLIB" includes a
03632 pointer, called @a err, to a wcserr struct.  When an error occurs, a struct is
03633 allocated and error information stored in it.  The wcserr pointers and the
03634 @ref memory "memory" allocated for them are managed by the routines that
03635 manage the various structs such as wcsinit() and wcsfree().
03636
03637 wcserr messaging is an opt-in system enabled via wcserr_enable(), as in the
03638 example above.  If enabled, when an error occurs it is the user's
03639 responsibility to free the memory allocated for the error message using
03640 wcsfree(), celfree(), prjfree(), etc.  Failure to do so before the struct goes
03641 out of scope will result in memory leaks (if execution continues beyond the
03642 error).
