The parameters of the shower module:

*(Shower core: parameters)*≡  
`real(default), save :: alphasxpdfmax = 12._default`

In this routine, `y` and `ymin` are the jet measures, `w` and `wmax` are weights, `s` is the kinematic energy squared of the interaction. The flag `isr_is_possible_and_allowed` checks whether the initial parton is set, lepton-hadron collisions are not implemented (yet).

As a workaround: as WHIZARD can treat partons as massless, there might be partons with  $E < m$ : if such a parton is found, quarks will be treated massless.

```

We combine the `particle_set` from the hard interaction with the partons of the shower. For simplicity, we do not maintain the mother-daughter-relations of the shower. Hadronic `beam_remnants` of the old `particle_set` are removed as they are provided, including proper flavor information, by the ISR shower.

!C      KTCLUS: written by Mike Seymour, July 1992.  
!C      Last modified November 2000.  
!C      Please send comments or suggestions to Mike.Seymour@rl.ac.uk  
!C  
!C      This is a general-purpose kt clustering package.  
!C      It can handle ee, ep and pp collisions.  
!C      It is loosely based on the program of Siggi Bethke.  
!C  
!C      The time taken (on a 10MIP machine) is (0.2microsec)*N**3  
!C      where N is the number of particles.  
!C      Over 90 percent of this time is used in subroutine KTPMIN, which  
!C      simply finds the minimum member of a one-dimensional array.  
!C      It is well worth thinking about optimization: on the SPARCstation  
!C      a factor of two increase was obtained simply by increasing the  
!C      optimization level from its default value.  
!C  
!C      The approach is to separate the different stages of analysis.  
!C      KTCLUS does all the clustering and records a merging history.  
!C      It returns a simple list of the y values at which each merging  
!C      occurred. Then the following routines can be called to give extra  
!C      information on the most recently analysed event.  
!C      KTCLUR is identical but includes an R parameter, see below.  
!C      KTYCUT gives the number of jets at each given YCUT value.  
!C      KTYSUB gives the number of sub-jets at each given YCUT value.  
!C      KTBEAM gives same info as KTCLUS but only for merges with the beam  
!C      KTJOIN gives same info as KTCLUS but for merges of sub-jets.  
!C      KTRECO reconstructs the jet momenta at a given value of YCUT.  
!C      It also gives information on which jets at scale YCUT belong to  
!C      which macro-jets at scale YMACH, for studying sub-jet properties.  
!C      KTINCL reconstructs the jet momenta according to the inclusive jet  
!C      definition of Ellis and Soper.  
!C      KTISUB, KTIJOI and KTIREC are like KTYSUB, KTJOIN and KTRECO,  
!C      except that they only apply to one inclusive jet at a time,  
!C      with the pt of that jet automatically used for ECUT.  
!C      KTWICH gives a list of which particles ended up in which jets.  
!C      KTWCHS gives the same thing, but only for subjects.  
!C      Note that the numbering of jets used by these two routines is  
!C      guaranteed to be the same as that used by KTRECO.  
!C  
!C      The collision type and analysis type are indicated by the first  
!C      argument of KTCLUS. IMODE=<TYPE><ANGLE><MONO><RECOM> where  
!C      TYPE:  1=>ee, 2=>ep with p in -z direction, 3=>pe, 4=>pp
```

```

!C      ANGLE: 1=>angular kt def., 2=>DeltaR, 3=>f(DeltaEta,DeltaPhi)
!C          where f()=2(cosh(eta)-cos(phi)) is the QCD emission metric
!C      MONO: 1=>derive relative pseudoparticle angles from jets
!C          2=>monotonic definitions of relative angles
!C      RECOM: 1=>E recombination scheme, 2=>pt scheme, 3=>pt**2 scheme
!C
!C      There are also abbreviated forms for the most common combinations:
!C      IMODE=1 => E scheme in e+e-                               (=1111)
!C          2 => E scheme in ep                                (=2111)
!C          3 => E scheme in pe                                (=3111)
!C          4 => E scheme in pp                                (=4111)
!C          5 => covariant E scheme in pp                  (=4211)
!C          6 => covariant pt-scheme in pp                (=4212)
!C          7 => covariant monotonic pt**2-scheme in pp    (=4223)
!C
!C      KTRECO no longer needs to reconstruct the momenta according to the
!C      same recombination scheme in which they were clustered. Its first
!C      argument gives the scheme, taking the same values as RECOM above.
!C
!C      Note that unlike previous versions, all variables which hold y
!C      values have been named in a consistent way:
!C      Y() is the output scale at which jets were merged,
!C      YCUT is the input scale at which jets should be counted, and
!C          jet-momenta reconstructed etc,
!C      YMAG is the input macro-jet scale, used in determining whether
!C          or not each jet is a sub-jet.
!C      The original scheme defined in our papers is equivalent to always
!C      setting YMAG=1.
!C      Whenever a YCUT or YMAG variable is used, it is rounded down
!C      infinitesimally, so that for example, setting YCUT=Y(2) refers
!C      to the scale where the event is 2-jet, even if rounding errors
!C      have shifted its value slightly.
!C
!C      An R parameter can be used in hadron-hadron collisions by
!C      calling KTCLUR instead of KTCLUS. This is as suggested by
!C      Ellis and Soper, but implemented slightly differently,
!C      as in M.H. Seymour, LU TP 94/2 (submitted to Nucl. Phys. B.).
!C      R**2 multiplies the single Kt everywhere it is used.
!C      Calling KTCLUR with R=1 is identical to calling KTCLUS.
!C      R plays a similar role to the jet radius in a cone-type algorithm,
!C      but is scaled up by about 40% (ie R=0.7 in a cone algorithm is
!C      similar to this algorithm with R=1).
!C      Note that R.EQ.1 must be used for the e+e- and ep versions,
!C      and is strongly recommended for the hadron-hadron version.
!C      However, R values smaller than 1 have been found to be useful for
!C      certain applications, particularly the mass reconstruction of
!C      highly-boosted colour-singlets such as high-pt hadronic Ws,
!C      as in M.H. Seymour, LU TP 93/8 (to appear in Z. Phys. C.).
!C      Situations in which R<1 is useful are likely to also be those in
!C      which the inclusive reconstruction method is more useful.
!C
!C      Also included is a set of routines for doing Lorentz boosts:
!C      KTLBST finds the boost matrix to/from the cm frame of a 4-vector
!C      KTRROT finds the rotation matrix from one vector to another

```

```

!C      KTMMUL multiplies together two matrices
!C      KTMUL multiplies a vector by a matrix
!C      KTINVT inverts a transformation matrix (nb NOT a general 4 by 4)
!C      KTFRAM boosts a list of vectors between two arbitrary frames
!C      KTBREI boosts a list of vectors between the lab and Breit frames
!C      KTHADR boosts a list of vectors between the lab and hadronic cmf
!C          The last two need the momenta in the +z direction of the lepton
!C          and hadron beams, and the 4-momentum of the outgoing lepton.
!C
!C      The main reference is:
!C          S. Catani, Yu.L. Dokshitzer, M.H. Seymour and B.R. Webber,
!C          Nucl.Phys.B406(1993)187.
!C      The ep version was proposed in:
!C          S. Catani, Yu.L. Dokshitzer and B.R. Webber,
!C          Phys.Lett.285B(1992)291.
!C      The inclusive reconstruction method was proposed in:
!C          S.D. Ellis and D.E. Soper,
!C          Phys.Rev.D48(1993)3160.

## Chapter 21

# Multiple Interactions (MPI) Code

This is the code for the WHIZARD module for multiple interactions (MPI) in hadron collisions. It also provides the interleaved shower with together with the shower module.

### 21.1 Basic types

This file contains the module `muli_basic` which is included by all other modules of the MPI code. It's main purpose is serialization and deserialization, but it also contains some bitmodel parameters and some minor definitions common to all modules and types.

Serialization is implemented in three layers:

1. **I/O layer**: streamfile access and exact, retrievable and compiler independent representation of all intrinsic types
2. **Marking layer**: storing/restoring pointer association and better human readability
3. **Derived type layer**: abstract type as parent for all serializable derived types

**The I/O Layer** The I/O layer is implemented by `page_ring_t` and its type bound procedures. We chose not to use the standard formatted sequential I/O for several reasons:

- Sequential I/O is line orientated, but serialization is not.
- Formatted I/O of floating point numbers is inexact. There were problems in reading numbers like `1+epsilon(1)` or `huge(1)` including arithmetic exceptions and wrong results.
- Formatted reading is slow. This does matter, when you read files of  $\mathcal{O}(100)$  MB.

`page_ring_t` is a ring buffer of default kind characters holding a region of the addressed file. All read and write procedures use the ring buffer, not the file. `page_ring` automatically reads more characters from the file when needed and writes and discards parts of the ring buffer when not any longer needed.

**Marking layer** Marking is done by `marking_t` and its type bound procedures. Files written by `marking_t` are regular XML files, so you can use your favorite XML editor to examine or edit serialized contents. The main purpose of this layer is to recover the type of polymorphic entities and to restore association of pointers, but it also assigns names to all contents, so it is much easier to read generated files.

Type recovery is done by a reference list. You must push a representative object to this reference list for each type that might get resolved before starting deserialization. `marker_t` will care for comparing these representatives to the contents of the files.

Association restoration is done by a heap list. It is technically equal to the reference list, but holds all targets that have been processed so far. Generation of this list is handled by `marking_t`, so you don't have to care for this aspect at all. Up to the present it is not possible to restore association, when a non-pointer target is serialized after its associated pointer is serialized. There is no trivial solution and this case does not appear here, so we will not take care of this.

**Derived type layer** Each instance that shall become serialized must extend `ser_class_t`. Essential for type recovery is the virtual type bound procedure `get_type`. Each non-virtual type shall override `get_type` and return the actual name of its type in lower-case letters. Each type which adds new, non-redundant components shall override `write_to_marker` and `read_from_marker`. These type-bound procedures define, what contents get serialized. While the marker cares about tagging the type and association of the instance, every instance still has to define what to serialize. The rule is to mark the begin of its contents, then its parents procedure, then mark all non-redundant components, then mark the end of its contents. Finally, each serializable type shall override `print_to_unit`. This procedure is called for an arbitrary human-readable output. It is quite similar to `write_to_ring`, but without strict format and ignoring machine-readability.

`ser_class_t` has strictly speaking two layers. `write_to_marker` and `read_from_marker` are only for internal usage. Serialization and deserialization are triggered by the TBPs serialize and deserialize. These procedures take care of initialization and finalization of the marker. A serializable type should override these procedures to push a representative of itself and any other references to the reference list of it's marker before (de)serialization and to pop them from the list afterwards.

## 21.2 Transverse momenta

This file contains the module `muli_momentum`. Its purpose is to store the actual value of the evolution parameter  $p_t^2$  in a convenient way. We use the normalized value  $p_t^2/p_{t,\max}^2$  for generating the next value of the scale, also need the square root of both  $p_t^2$  and  $p_t^2/p_{t,\max}^2$  for other purposes. That's why I store all four combinations together with  $p_{t,\max}$  in an array.

```

### 21.3 Multi parton interactions

This file contains the module `muli_interactions`. The allowed interactions and their cross sections are defined here. Additionally, some coordinate transformations which annihilate divergencies of the cross sections are defined. Since the phase space border is hyperbolic, these transformations are also hyperbolic. That's why all interactions are named `x_cart` for cartesian or `x_hyp` for hyperbolic to avoid confusion.

## 21.4 VEGAS and CUBA integration routines

This file contains the module `muli_cuba`, a wrapper for the CUBA integration library. Different algorithms and settings have been tried out for the integration, including VEGAS, and this wrapper has been mainly written for that purpose.

```

## 21.5 Trapezoidal integration routines

This file contains the module "muli\_trapezium". The name is derived from the trapezoidal integration rule. The purpose of this module is to define a binary tree `muli_trapezium_tree_t` which holds a probability function in terms of trapezoidal segments. Its leaves of type `muli_trapezium_list_t` are connected to form a list, so you can either walk the root function back and forth or pick a certain segment in logarithmic time by walking down the tree. All nodes extend `muli_trapezium_t` which holds the actual values. Those are the values of the density function, the integral from this segment to the end of the integration area and a probability function calculated from these values. All values are taken at the upper "right" bound of the segment. Additionally the differences of these values to the values of the left neighbor is stored.

```

```

This is the base type `muli_trapezium_t`. Its component values has a first index is in  $\{0, \dots, \text{dim} - 1\}$ , while the second index distinguishes between `r_value`, `d_value`, `r_integral`, `d_integral`, `r_probability`, `d_probability`.

## 21.6 Fibonacci trees

This file contains the module `muli_fibonacci_tree`. A fibonacci tree is a self-balancing binary tree. "Balanced" means that the depth of the left successor may differ from the depth of the right successor in any node by maximally one. The maximally unbalanced tree is maximally unbalanced in every node. So the number of leaves of a maximally unbalanced fibonacci tree of depth  $n$  is precisely the  $n$ th fibonacci number.

We use this tree for the adaptive quadrature. In every iteration of the algorithm, we have to pick the segment with largest integration error, cut it into pieces and calculate the new integration error for the pieces. A binary tree is obviously a good choice for sorting these segments. The problem is, that we always pick leaves from the same side of the tree. So the tree must decline at one side and grow at the other side. Sorting gets less efficient and finally most of the overall CPU time gets wasted for sorting. This tree outperforms a naive binary tree significantly in this particular job.

## 21.7 Adaptive Quadrature

This file contains the module `muli_aq` which is an acronym for adaptive quadrature. The abstract type `aq_class` is extended and the deferred procedure `evaluate` is defined. `muli_aq` calls `evaluate` to evaluate the integrand at any point in the given range. We have tried to use a procedure pointer instead of the deferred type-bound procedure, but no compiler was able to handle procedure pointers plus cuba was not able to handle parameters, to wit dimensions of the integrand that should not get integrated. So we switched to this odd way of using inheritance. Meanwhile these problems got solved and we could go for a more straightforward solution, but it works fine as it is.

`aq_class` uses `muli_trapezium` to approximate the integral. It still has to do the subdivision of segments and has to check whether the precision goal is reached.

Finally, the result is written to disc using the serialization framework defined in `muli_base`. Since QCD is not expected to change frequently, the only reason to regenerate this function is a change of the used PDF set. Then you can read the integral from disc each time you run a simulation with the same PDF set.

`(muli_aq.f90)≡`

*(File header)*

```
module muli_aq
```

*(Use kinds)*

```
use constants
use diagnostics
use muli_base
use muli_cuba
use muli_trapezium

```

*(Standard module head)*

*(Muli aq: public)*

*(Muli aq: types)*

*(Muli aq: interfaces)*

**contains**

*(Muli aq: procedures)*

```
end module muli_aq
```

The variables `error_goal`, `err_tree` and `int_list` must be initialised before the main loop can be called. Additionally, the nodes and segments should be preprocessed by `first_run` before the main loop is called.

```

Usually, the tree is sorted by the sum of errors. Now it shall be sorted by the right position. When at least one branch of the tree is itself a tree, i.e. each branch has got at least two leaves, then process each branch and merge the results. Now we got two sorted lists. Which one's leftmost node has got the lowest value of `r_position`? That one shall be the beginning of the merged list `lin_list`. Everything is prepared for the algorithm: `lin_list` is the beginning of the sorted list, `last_node` is its end. `left_node` and `right_node` are the leftmost nodes of the remainders of `left_list` and `right_list`. The latter will get stripped from left to right, until one of them ends. Then, either `left_list` or `right_list` is completely merged into `lin_list`. The other one gets appended to `lin_list`. In the second part of the big if clause, the tree has got two leaves at most. Is it more than one? There, `fib_tree` is a single leave with an allocated "content" component of type `muli_trapezium_t`. If "content" is not type-compatible with `muli_trapezium_t`, then this whole conversion cannot succeed. We allocate a new node of type `muli_trapezium_list_t`. This list does not contain the content of `fib_tree`, it is a copy of the content, for `muli_trapezium_list_t` is an extension of `muli_trapezium_t`. In the next step, each branch of `fib_tree` is a single leave. We could call this subroutine for each branch, but we do copy and paste for each branch instead. Finally we append one list to the other, the lowest value of `r_position` comes first.

## 21.8 Integrands for Multiple Interactions

This file contains the module `muli_dsigma`. Its only type `muli_dsigma_t` provides an integrand to `aq_class`. The actual integrand is the normalized differential cross section of a QCD  $2 \rightarrow 2$  process  $1/\sigma_0 \times d^3\sigma/(dp_T^2 dx_1 dx_2)$ . We need a root function of this integrand in terms of  $p_T$ , so we have to integrate out  $x_1$  and  $x_2$  and have to approximate the root function of the leftover variable  $p_T$ .

Integration of  $x_1$  and  $x_2$  is done by CUBA, the root function is approximated by `muli_aq`.

## 21.9 MC Integrations for QCD $2 \rightarrow 2$ processes

This file contains the module `muli_mcint` which is the Monte Carlo generator for QCD  $2 \rightarrow 2$  interactions at given evolution parameter and given stratus. While `muli_t` takes care of generating the evolution parameter and the stratus, this module is about bookkeeping the strati and implementing a downstream importance sampling. The evolution parameter is a measure of transferred momentum and a “stratus” is a PDF category or, to be more precise, is whether the incoming partons are gluons or sea quarks or valence quarks.

The importance sampling then subdivides the phase space of variables  $\{x_1, x_2, p_T\}$  into  $n^3$  regions such that each region holds approximately  $n$  interactions. Thus, we can generate a phase space point very quickly just by randomly picking a region, randomly picking a point within this region and comparing its exact cross section with the mean cross section for this actual evolution parameter and the actual stratus times the area of the picked phase space region.

The mean values must be generated in the module `muli_dsigma` before and are given to the procedure `sample_inclusive_generate_hit`. Finally the generated subregions should be written to a file via `write_to_marker` and then reused for each later WHIZARD run.

The type `sample_inclusive_t` holds the 16 strati, while the type `sample_int_kind_t` represents a single stratus, `sample_3d_t` is the whole  $\{x_1, x_2, p_T\}$  phase space for each stratus, `sample_2d_t` is the  $\{x_1, x_2\}$  plane with a slice of  $p_T$  and `sample_region_t` finally is a phase space region.

## 21.11 The Multiple Interactions main module

This file contains the module `muli` which is the multiple parton interactions interface module to `WHIZARD`. `muli` is supposed to run together with initial state radiation. Both share a momentum evolution variable and compete for beam momentum, so the generation of this scale variable must be fully transparent to `WHIZARD`. That is why the corresponding procedures are here, while all other work like phase space integration, flavor generation and treatment of the beam remnant is put into `muli_dsigma`, `muli_mcint` and `muli_remnant`, respectively.

`qcd_2_2_t` is a container class for properties of QCD  $2 \rightarrow 2$  interactions. It holds a very condensed internal representation and offers a convenient set of TBP to query all aspects without the burden of the generator internals.

`muli_t` then is an extension of `qcd_2_2_t` that adds generator internals like random number generator, integrated cross-sections, the actual Monte Carlo generator for flavor generation and beam remnants in `tao_rnd`, `dsigma`, `samples` and `beam`, respectively.

end function qcd_2_2_get_diagram_kind

```

This is one more hack. Before merging into the interleaved algorithm, `muli` has only cared for summed cross sections, but not in specific color flows. So two different diagrams with equal cross sections were summed up to diagram kind 1. Now `muli` also generates color flows, so we must devide diagram kind 1 into diagram color kind 0 and diagram color kind 1.

# Chapter 22

# User Plugin Support

Here we collect interface code that enables the user to inject his own code into the WHIZARD workflow. The code uses data types defined elsewhere, and is referenced in the `eval_trees` module.

These are the modules:

**user\_code\_interface** Generic support and specific additions.

**sf\_user** Handle user-defined structure functions.

## 22.1 User Code Interface

```
<user_code_interface.f90>≡
  <File header>

  module user_code_interface

    use iso_c_binding !NODEP!
    <Use kinds>
    <Use strings>
      use diagnostics
      use c_particles
      use os_interface

    <Standard module head>

    <User Code: public>
    <User Code: variables>
    <User Code: interfaces>

    contains

    <User Code: procedures>

  end module user_code_interface
```

### 22.1.1 User Code Management

This data structure globally holds the filehandle of the user-code library:

```
<User Code: public>≡
  public :: has_user_lib
<User Code: variables>≡
  type(dlaccess_t), save :: user_lib_handle
  logical, save :: has_user_lib = .false.
  type(string_t), save :: user
```

Compile, link and load user code files. Dlopen all user-provided libraries, included the one just compiled (if any).

By default, we are looking for a library `user.so/dylib`. If this is not present, try `user.f90` and compile it. This can be overridden.

In detail: First, compile all sources explicitly specified on the command line. Then collect all libraries specified on the command line, including `user.so` if it was generated. If there is still no code, check for an existing `user.f90` and compile this. Link everything into a `user.la` libtool library. When done, dlopen all libraries that we have so far.

```
<User Code: public>+≡
  public :: user_code_init
```

```

⟨User Code: procedures⟩≡
subroutine user_code_init (user_src, user_lib, user_target, rebuild, os_data)
    type(string_t), dimension(:), intent(in) :: user_src, user_lib

### 22.1.2 Interfaces for user-defined functions

The following functions represent user-defined real observables. There may be one or two particles as argument, the result is a real value.

```

⟨User Code: public⟩+≡
    public :: user_obs_int_unary
    public :: user_obs_int_binary
    public :: user_obs_real_unary
    public :: user_obs_real_binary

⟨User Code: interfaces⟩≡
    abstract interface
        function user_obs_int_unary (prt1) result (ival) bind(C)
            use iso_c_binding !NODEP!

```

```

use c_particles !NODEP!
type(c_prt_t), intent(in) :: prt1
integer(c_int) :: ival
end function user_obs_int_unary
end interface

abstract interface
    function user_obs_int_binary (prt1, prt2) result (ival) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        integer(c_int) :: ival
    end function user_obs_int_binary
end interface

abstract interface
    function user_obs_real_unary (prt1) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1
        real(c_double) :: rval
    end function user_obs_real_unary
end interface

abstract interface
    function user_obs_real_binary (prt1, prt2) result (rval) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), intent(in) :: prt1, prt2
        real(c_double) :: rval
    end function user_obs_real_binary
end interface

```

The following function takes an array of C-compatible particles and return a single value. The particle array represents a subevent. For C interoperability, we have to use an assumed-size array, hence the array size has to be transferred explicitly.

The cut function returns an `int`, which we should interpret as a logical value (`nonzero=true`).

```

<User Code: public>+≡
public :: user_cut_fun

<User Code: interfaces>+≡
abstract interface
    function user_cut_fun (prt, n_prt) result (iflag) bind(C)
        use iso_c_binding !NODEP!
        use c_particles !NODEP!
        type(c_prt_t), dimension(*), intent(in) :: prt
        integer(c_int), intent(in) :: n_prt
        integer(c_int) :: iflag
    end function user_cut_fun
end interface

```

The event-shape function returns a real value.

```
User Code: public+≡
    public :: user_event_shape_fun

User Code: interfaces+≡
    abstract interface
        function user_event_shape_fun (prt, n_prt) result (rval) bind(C)
            use iso_c_binding !NODEP!
            use c_particles !NODEP!
            type(c_prt_t), dimension(*), intent(in) :: prt
            integer(c_int), intent(in) :: n_prt
            real(c_double) :: rval
        end function user_event_shape_fun
    end interface
```

### 22.1.3 Interfaces for user-defined interactions

The following procedure interfaces pertain to user-defined interactions, e.g., spectra or structure functions.

This subroutine retrieves the basic information for setting up the interaction and event generation. All parameters are `intent(inout)`, so we can provide default values. `n_in` and `n_out` are the number of incoming and outgoing particles, respectively. `n_states` is the total number of distinct states that should be generated (counting all states of the incoming particles). `n_col` is the maximal number of color entries a particle can have. `n_dim` is the number of input parameters, i.e., integration dimensions, that the structure function call requires for computing kinematics and matrix elements. `n_var` is the number of variables (e.g., momentum fractions) that the structure function call has to transfer from the kinematics to the dynamics evaluation.

```
User Code: public+≡
    public :: user_int_info

User Code: interfaces+≡
    abstract interface
        subroutine user_int_info (n_in, n_out, n_states, n_col, n_dim, n_var) &
            bind(C)
            use iso_c_binding !NODEP!
            integer(c_int), intent(inout) :: n_in, n_out, n_states, n_col
            integer(c_int), intent(inout) :: n_dim, n_var
        end subroutine user_int_info
    end interface
```

This subroutine retrieves the settings for the quantum number mask of a given particle index in the interaction. A nonzero value indicates that the corresponding quantum number is to be ignored. The lock index is the index of a particle that the current particle is related to. The relation applies if quantum numbers of one of the locked particles are summed over. (This is intended for helicity.)

```
User Code: public+≡
    public :: user_int_mask
```

```

⟨User Code: interfaces⟩+≡
  abstract interface
    subroutine user_int_mask (i_prt, m_flv, m_hel, m_col, i_lock) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_prt
      integer(c_int), intent(inout) :: m_flv, m_hel, m_col, i_lock
    end subroutine user_int_mask
  end interface

```

This subroutine retrieves the quantum numbers for the particle index `i_prt` in state `i_state`. The `flv` value is a PDG code. The `hel` value is an integer helicity (twice the helicity for fermions). The `col` array is an array which has at most `n_col` entries (see above). All parameters are `intent(inout)` since default values exist. In particular, if a mask entry is set by the previous procedure, the corresponding quantum number is ignored anyway.

```

⟨User Code: public⟩+≡
  public :: user_int_state

⟨User Code: interfaces⟩+≡
  abstract interface
    subroutine user_int_state (i_state, i_prt, flv, hel, col) bind(C)
      use iso_c_binding !NODEP!
      integer(c_int), intent(in) :: i_state, i_prt
      integer(c_int), intent(inout) :: flv, hel
      integer(c_int), dimension(*), intent(inout) :: col
    end subroutine user_int_state
  end interface

```

This subroutine takes an array of particle objects with array length `n_in` and an array of input parameters between 0 and 1 with array length `n_dim`. It returns an array of particle objects with array length `n_out`. In addition, it returns an array of internal variables (e.g., momentum fractions, Jacobian) with array length `n_var` that is used by the following subroutine for evaluating the dynamics, i.e., the matrix elements.

```

⟨User Code: public⟩+≡
  public :: user_int_kinematics

⟨User Code: interfaces⟩+≡
  abstract interface
    subroutine user_int_kinematics (prt_in, rval, prt_out, xval) bind(C)
      use iso_c_binding !NODEP!
      use c_particles !NODEP!
      type(c_prt_t), dimension(*), intent(in) :: prt_in
      real(c_double), dimension(*), intent(in) :: rval
      type(c_prt_t), dimension(*), intent(inout) :: prt_out
      real(c_double), dimension(*), intent(out) :: xval
    end subroutine user_int_kinematics
  end interface

```

This subroutine takes the array of variables (e.g., momentum fractions) with length `n_var` which has been generated by the previous subroutine and a real variable, the energy scale of the event. It returns an array of matrix-element

values, one entry for each quantum state `n_states`. The ordering of matrix elements must correspond to the ordering of states.

```
<User Code: public>+≡  
    public :: user_int_evaluate  
<User Code: interfaces>+≡  
    abstract interface  
        subroutine user_int_evaluate (xval, scale, fval) bind(C)  
            use iso_c_binding !NODEP!  
            real(c_double), dimension(*), intent(in) :: xval  
            real(c_double), intent(in) :: scale  
            real(c_double), dimension(*), intent(out) :: fval  
        end subroutine user_int_evaluate  
    end interface
```

## 22.2 User Plugin for Structure Functions

This variant gives access to user-defined structure functions or spectra.

### 22.2.1 The module

```
<sf_user.f90>≡  
    <File header>  
  
    module sf_user  
  
        use, intrinsic :: iso_c_binding !NODEP!  
        <Use kinds>  
        <Use strings>  
        use io_units  
        use format_defs, only: FMT_17  
        use diagnostics  
        use c_particles  
        use lorentz  
        use subevents  
        use user_code_interface  
        use pdg_arrays  
        use model_data  
        use flavors  
        use helicities  
        use colors  
        use quantum_numbers  
        use state_matrices  
        use polarizations  
        use interactions  
        use sf_aux  
        use sf_base  
  
    <Standard module head>  
  
    <SF user: public>
```

```

⟨SF user: types⟩
contains
⟨SF user: procedures⟩
end module sf_user

```

### 22.2.2 The user structure function data block

The data block holds the procedure pointers that are used for retrieving static information, as well as the actual evaluation.

```

⟨SF user: public⟩≡
public :: user_data_t
⟨SF user: types⟩≡
type, extends(sf_data_t) :: user_data_t
private
type(string_t) :: name
integer :: n_in
integer :: n_out
integer :: n_tot
integer :: n_states
integer :: n_col
integer :: n_dim
integer :: n_var
integer, dimension(2) :: pdg_in
class(model_data_t), pointer :: model => null ()
procedure(user_int_info), nopass, pointer :: info => null ()
procedure(user_int_mask), nopass, pointer :: mask => null ()
procedure(user_int_state), nopass, pointer :: state => null ()
procedure(user_int_kinematics), nopass, pointer :: kinematics => null ()
procedure(user_int_evaluate), nopass, pointer :: evaluate => null ()
contains
⟨SF user: user data: TBP⟩
end type user_data_t

```

Assign procedure pointers from a dynamically loaded library, given the specified name.

We have to distinguish three cases: (1) Both beams are affected, and the user spectrum implements both beams. There is a single data object. (2) Both beams are affected, and the user spectrum applies to single beams. Fill two different objects. (3) A single beam is affected.

```

⟨SF User: public⟩≡
public :: sf_user_data_init
⟨SF User: procedures⟩≡

```

### 22.2.3 The interaction

We fill the interaction by looking up the table of states using the interface functions.

For particles which have a known flavor (as indicated by the mask), we compute the mass squared, so we can use it for the invariant mass of the particle objects.

```
⟨SF user: user: TBP⟩≡
procedure :: init => user_init
```

```

#### 22.2.4 The user structure function

For maximal flexibility, user structure functions separate kinematics from dynamics just as the PDF interface does. (JRR: Ok, I guess this now done for all structure functions, right?) We create `c_prt_t` particle objects from the incoming momenta (all other quantum numbers are irrelevant) and call the user-supplied kinematics function to compute the outgoing momenta, along with other variables that will be needed for matrix element evaluation. If known, we use the mass squared computed above. !!! JRR: WK please check (#529) I don't know actually whether this really fits into the setup done by WK.

```

⟨SF user: types⟩+≡

```

### 22.2.5 Kinematics

Set kinematics. If `map` is unset, the  $r$  and  $x$  values coincide, and the Jacobian  $f(r)$  is trivial.

If `map` is set, we are asked to provide an efficient mapping. For the test case, we set  $x = r^2$  and consequently  $f(r) = 2r$ .

```

<SF user: user: TBP>+≡
procedure :: complete_kinematics => user_complete_kinematics

```

# Chapter 23

## BLHA Interface

The code in this chapter implements support for the BLHA record that communicates data for NLO processes.

These are the modules:

```
blha_config  
blha_interface  
blha_driver
```

### 23.1 Module definition

These modules implement the communication with one loop matrix element providers according to the Binoth LesHouches Accord Interface. The actual matrix element(s) are loaded as a dynamic library.

This module defines the common OLP-interfaces defined through the Binoth Les-Houches accord.

```

```

We have to add two O'Mega-routines to the BLHA driver to ensure proper process setup. The problem is that during the setup of the real component, the particle and flavor data are taken from the Born component to set up the subtraction terms. However, the Born component expects this data to be obtained from the Omega code, accessed by the driver.

Compute the Born matrix element. This will always occur in connection to a subtraction term, so scales and couplings have already been set, and the momenta are in the BLHA format. Hence, the interface is simpler than in the other routines.

# Chapter 24

## GoSam Interface

The code in this chapter makes amplitudes accessible to **WHIZARD** that are generated and computed by the GoSam package.

These are the modules:

**loop\_archive** Provide some useful extra functionality.

**prc\_gosam** The actual interface, following the **WHIZARD** conventions for matrix-element generator methods.

## 24.1 Save previously generated loop libraries

```
<loop_archive.f90>≡

```

The BLHA-interface conventions require the quantity  $S_{ij} = \langle M_{i,+}|T_i T_j| M_{i,-} \rangle$  to be produced, where  $i$  is the position of the splitting gluon. However,  $\tilde{M} = \langle M_{i,-}|M_{i,+} \rangle$  is needed. This can be obtained using color conservation,  $\sum_j T_j|M\rangle = 0$ , so that

$$\sum_{j \neq i} S_{ij} = -\langle M_{i,+}|T_i^2|M_{i,-} \rangle = -C_A \langle M_{i,+}|M_{i,-} \rangle = -C_A \tilde{M}^*$$

According to BLHA conventions, the real part of  $S_{ij}$  is located at positions  $2i + 2nj$  in the output array, where  $n$  denotes the number of external particles

and the enumeration of particles starts at zero. The subsequent position, i.e.  $2i + 2nj + 1$  is designated to the imaginary part of  $S_{ij}$ . Note that, since the first array position is 1, the implemented position association deviates from the above one in the addition of 1.

# Chapter 26

## FKS Subtraction Scheme

The code in this chapter implements the FKS subtraction scheme for use with **WHIZARD**.

These are the modules:

**fks\_regions** Given a process definition, identify singular regions in the associated phase space.

**virtual** Handle the virtual correction matrix element.

**real\_subtraction** Handle the real-subtraction matrix element.

**nlo\_data** Manage the subtraction objects.

**phs\_fks** Phase-space parameterization with modifications for the FKS scheme.

This chapter deals with next-to-leading order contributions to cross sections. Basically, there are three major issues to be addressed: The creation of the  $N+1$ -particle flavor structure, the construction of the  $N+1$ -particle phase space and the actual calculation of the real- and virtual-subtracted matrix elements. The first is dealt with using the `auto_components` class, and it will be shown that the second and third issue are connected in FKS subtraction.

### 26.1 Brief outline of FKS subtraction

*In the current state, this discussion is only concerned with lepton collisions. For hadron collisions, renormalization of parton distributions has to be taken into account. Further, for QCD corrections, initial-state radiation is necessarily present. However, most quantities have so far been only constructed for final-state emissions*

The aim is to calculate the next-to-leading order cross section according to

$$d\sigma_{\text{NLO}} = \mathcal{B} + \mathcal{V} + \mathcal{R}d\Phi_{\text{rad}}.$$

Analytically, the divergences, in terms of poles in the complex quantity  $\varepsilon = 2 - d/2$ , cancel. However, this is in general only valid in an arbitrary, complex number of dimensions. This is, roughly, the content of the KLN-theorem. **WHIZARD**, as any other numerical program, is confined to four dimensions. We will assume

that the KLN-theorem is valid and that there exist subtraction terms  $\mathcal{C}$  such that

$$d\sigma_{\text{NLO}} = \mathcal{B} + \underbrace{\mathcal{V}}_{\text{finite}} + \underbrace{\mathcal{C} + \mathcal{R} - \mathcal{C}}_{\text{finite}},$$

i.e. the subtraction terms correspond to the divergent limits of the real and virtual matrix element.

Because  $\mathcal{C}$  subtracts the divergences of  $\mathcal{R}$  as well as those of  $\mathcal{V}$ , it suffices to consider one of them, so we focus on  $\mathcal{R}$ . For this purpose,  $\mathcal{R}$  is rewritten,

$$\mathcal{R} = \frac{1}{\xi^2} \frac{1}{1-y} (\xi^2(1-y)\mathcal{R}) = \frac{1}{\xi^2} \frac{1}{1-y} \tilde{\mathcal{R}},$$

with  $\xi = (2k_{\text{rad}}^0)/\sqrt{s}$  and  $y = \cos\theta$ , where  $k_{\text{rad}}^0$  denotes the energy of the radiated parton and  $\theta$  is the angle between emitter and radiated parton.  $\tilde{\mathcal{R}}$  is finite, therefore the whole singularity structure is contained in the prefactor  $\xi^{-2}(1-y)^{-1}$ . Combined with the d-dimensional phase space element,

$$\frac{d^{d-1}k}{2k^0(2\pi)^{d-1}} = \frac{s^{1-\varepsilon}}{(4\pi)^{d-1}} \xi^{1-2\varepsilon} (1-y^2)^{-\varepsilon} d\xi dy d\Omega^{d-2},$$

this yields

$$d\Phi_{\text{rad}} \mathcal{R} = dy(1-y)^{-1-\varepsilon} d\xi \xi^{-1-2\varepsilon} \tilde{\mathcal{R}}.$$

This can further be rewritten in terms of plus-distributions,

$$\begin{aligned} \xi^{-1-2\varepsilon} &= -\frac{1}{2\varepsilon} \delta(\xi) + \left(\frac{1}{\xi}\right)_+ - 2\varepsilon \left(\frac{\log \xi}{\xi}\right)_+ + \mathcal{O}(\varepsilon^2), \\ (1-y)^{-1-\varepsilon} &= -\frac{2^{-\varepsilon}}{\varepsilon} \delta(1-y) + \left(\frac{1}{1-y}\right)_+ - \varepsilon \left(\frac{1}{1-y}\right)_+ \log(1-y) + \mathcal{O}(\varepsilon^2), \end{aligned}$$

(imagine that all this is written inside of integrals, which are spared for ease of notation) such that

$$\begin{aligned} d\Phi_{\text{rad}} \mathcal{R} &= -\frac{1}{2\varepsilon} dy(1-y)^{-1-\varepsilon} \tilde{\mathcal{R}}(0, y) - d\xi \left[ \frac{2^{-\varepsilon}}{\varepsilon} \left(\frac{1}{\xi}\right)_+ - 2 \left(\frac{\log \xi}{\xi}\right)_+ \right] \tilde{\mathcal{R}}(\xi, 1) \\ &\quad + dy d\xi \left(\frac{1}{\xi}\right)_+ \left(\frac{1}{1-y}\right)_+ \tilde{\mathcal{R}}(\xi, y) + \mathcal{O}(\varepsilon). \end{aligned}$$

The summand in the second line is of order  $\mathcal{O}(1)$  and is the only one to reproduce  $\mathcal{R}\xi, y$ . It thus constitutes the sum of the real matrix element and the corresponding counterterms. The first summand consequently consists of the subtraction terms to the virtual matrix elements. Above formula thus allows to calculate all quantities to render the matrix elements finite.

Table 26.1: List of singular regions. The particles are represented by their PDG codes. The third column contains the emitter for the specific singular region. For the process involving an additional gluon, the gluon can either be emitted from one of the quarks or from the first gluon. Each emitter yields the same list of fundamental tuples, five in total. The last singular region corresponds to the process where the gluon splits up into two quarks. Here, there is only one fundamental tuple, corresponding to a singular configuration of the momenta of the additional quarks.

## 26.2 Identifying singular regions

In the FKS subtraction scheme, the phase space is decomposed into disjoint singular regions, such that

$$\sum_i \mathcal{S}_i + \sum_{ij} \mathcal{S}_{ij} = 1. \quad (26.1)$$

The quantities  $\mathcal{S}_i$  and  $\mathcal{S}_{ij}$  are functions of phase space corresponding to a pair of particles indices which can make up a divergent phase space region. We call such an index pair a fundamental tuple. For example, the process  $e^+ e^- \rightarrow u \bar{u} g$  has two singular regions,  $(3, 5)$  and  $(4, 5)$ , indicating that the gluon can be soft or collinear with respect to either the quark or the anti-quark. Therefore, the functions  $\mathcal{S}_{ij}$  have to be chosen in such a way that their contribution makes up most of (26.1) in phase-space configurations where (final-state) particle  $j$  is collinear to particle  $i$  or/and particle  $j$  is soft. The functions  $\mathcal{S}_i$  is the corresponding quantity for initial-state divergences.

As a singular region we understand the collection of real flavor structures associated with an emitter and a list of all possible fundamental tuples. As an example, consider the process  $e^+ e^- \rightarrow u \bar{u} g$ . At next-to-leading order, processes with an additionally radiated particle have to be considered. In this case, these are  $e^+ e^- \rightarrow u \bar{u}$ ,  $g g$ , and  $e^+ e^- \rightarrow u \bar{u} u \bar{u}$  (or the same process with any other quark). Table 26.2 sums up all possible singular regions for this problem.

Thus, during the preparation of a NLO-calculation, the possible singular regions have to be identified. `fks_regions.f90` deals with this issue.

    integer :: nlegs
    logical, dimension(:), allocatable :: massive
    logical, dimension(:), allocatable :: colored
  contains
    ⟨fks regions: flv structure: TBP⟩
  end type flv_structure_t

```

Returns **true** if the two particles at position *i* and *j* in the flavor array can originate from the same splitting. For this purpose, the function first checks whether the splitting is allowed at all. If this is the case, the emitter is removed from the flavor array. If the resulting array is equivalent to the Born flavor structure **flv\_born**, the pair is accepted as a valid splitting.

```

⟨fks regions: flv structure: TBP⟩≡
  procedure :: valid_pair => flv_structure_valid_pair
⟨fks regions: procedures⟩+≡
  function flv_structure_valid_pair &
    (flv_real,i,j, flv_born, model) result (valid)
    class(flv_structure_t), intent(in) :: flv_real
    integer, intent(in) :: i,j
    type(flv_structure_t), intent(in) :: flv_born
    type(model_data_t), intent(in) :: model
    logical :: valid
    integer :: k, n_orig
    type(flv_structure_t) :: flv_test
    integer, dimension(:), allocatable :: flv_orig, flv_orig2
    valid = .false.

```

First check whether the splitting is possible. The array **flv\_orig** contains all particles which share a vertex with the particles at position *i* and *j*. If its size is equal to zero, no splitting is possible and the subroutine is exited.

```

⟨fks regions: procedures⟩+≡
  call model%match_vertex &
    (flv_real%flst(i), flv_real%flst(j), flv_orig)
  n_orig = size (flv_orig)
  if (n_orig == 0) then
    return
  else

```

For a quark emitting a gluon, **flv\_orig** contains the PDG code of the anti-quark. To be on the safe side, a second array is created, which contains both the positively and negatively signed PDG codes. Then, the original tuple (*i*,*j*) is removed from the real flavor structure and the particles in **flv\_orig2** are inserted. If the resulting Born configuration is equal to the underlying Born configuration, up to a permutation of final-state particles, the tuple (*i*,*j*) is accepted as valid.

```

⟨fks regions: procedures⟩+≡
  allocate (flv_orig2 (2*n_orig))
  flv_orig2 (1:n_orig) = flv_orig
  flv_orig2 (n_orig+1:2*n_orig) = -flv_orig

```

```

do k = 1, 2*n_orig
    flv_test = flv_real%insert_particle (i,j,flv_orig2(k))
    valid = flv_born == flv_test
    if (valid) return
end do
end if
end function flv_structure_valid_pair

```

This function checks whether two flavor arrays are the same up to a permutation of the final-state particles

In case of a  $g \rightarrow gg$  or  $g \rightarrow qq$  splitting, the factor

$$\frac{2E_{\text{em}}}{E_{\text{em}} + E_{\text{rad}}}$$

is multiplied to the real matrix element. This way, the symmetry of the splitting is used and only one singular region has to be taken into account. However, the factor ensures that there is only a soft singularity if the radiated parton becomes soft.

```

This subroutine starts with a specification of  $N$ - and  $N + 1$ -particle configurations, `flst_born` and `flst_real`, saved in `reg_data`. From these, it creates a list of fundamental tuples, a list of emitters and a list containing the  $N + 1$ -particle configuration, rearranged in such a way that the emitter-radiation pair is last (`flst_alr`). For the  $e^+ e^- \rightarrow u \bar{u} g$ -example, the generated objects are shown in table 26.2. Note that at this point, `flst_alr` is arranged in such a way that the emitter can only be equal to  $n_{legs} - 1$  for final-state radiation or 0, 1, or 2 for initial-state radiation. Further, it occurs that regions can be equivalent. For example in table 26.2 the regions corresponding to `alr = 1` and `alr = 3` as well as `alr = 2` and `alr = 4` describe the same physics and are therefore equivalent.

The virtual-subtracted matrix element is given by the equation

$$\mathcal{V} = \frac{\alpha_s}{2\pi} \left( \mathcal{Q}\mathcal{B} + \sum \mathcal{I}_{ij}\mathcal{B}_{ij} + \mathcal{V}_{fin} \right), \quad (26.2)$$

where the quantity  $\mathcal{Q}$  is given by

$$\begin{aligned}
\mathcal{Q} = & \sum_{i=3}^n \left[ \gamma'_{f_i} - \log \frac{s}{Q^2} \left( \gamma_{f_i} - 2C_{f_i} \log \frac{2E_i}{\sqrt{s}} \right) \right. \\
& + 2C_{f_i} \log^2 \frac{2E_i}{\sqrt{s}} - 2\gamma_{f_i} \frac{2E_i}{\sqrt{s}} \Big] \\
& - \log \frac{\mu_F^2}{Q^2} (\gamma_{f+} + \gamma_{f-}).
\end{aligned} \quad (26.3)$$

Note that the summation only runs over final-state particles. The expressions for  $\mathcal{I}_{ij}$  can be found in equations (26.4), (26.5), (26.6), depending on whether the particles involved in the radiation process are massive or massless.

The following code implements the  $\mathcal{I}_{ij}$ -function appearing in eq. blub. They are defined as follows:

Massles-Massles Case

$$\begin{aligned} \mathcal{I}_{ij} &= \frac{1}{2} \log^2 \frac{s}{Q^2} + \log \frac{s}{Q^2} \log \frac{k_i k_j}{2E_i E_j} - \text{Li}_2 \left( \frac{k_i k_j}{2E_i E_j} \right) \\ &\quad + \frac{1}{2} \log^2 \frac{k_i k_j}{2E_i E_j} - \log \left( 1 - \frac{k_i k_j}{2E_i E_j} \right) \log \frac{k_i k_j}{2E_i E_j}. \end{aligned} \quad (26.4)$$

Massive-Massive Case

$$\mathcal{I}_{ij} = -\frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (26.5)$$

with

$$I_0(k_i, k_j) = \frac{1}{\beta} \log \frac{1+\beta}{1-\beta}, \quad \beta = \sqrt{1 - \frac{k_i^2 k_j^2}{(k_i \cdot k_j)^2}}$$

and a rather involved expression for  $I_\epsilon$ :

$$\begin{aligned}
I_\epsilon(k_i, k_j) &= (K(z_j) - K(z_i)) \frac{1 - \vec{\beta}_i \cdot \vec{\beta}_j}{\sqrt{a(1-b)}}, \\
\vec{\beta}_i &= \frac{\vec{k}_i}{k_i^0}, \\
a &= \beta_i^2 + \beta_j^2 - 2\vec{\beta}_i \cdot \vec{\beta}_j, \\
x_i &= \frac{\beta_i^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a}, \\
x_j &= \frac{\beta_j^2 - \vec{\beta}_i \cdot \vec{\beta}_j}{a} = 1 - x_j, \\
b &= \frac{\beta_i^2 \beta_j^2 - (\vec{\beta}_i \cdot \vec{\beta}_j)^2}{a}, \\
c &= \sqrt{\frac{b}{4a}}, \\
z_+ &= \frac{1 + \sqrt{1-b}}{\sqrt{b}}, \\
z_- &= \frac{1 - \sqrt{1-b}}{\sqrt{b}}, \\
z_i &= \frac{\sqrt{x_i^2 + 4c^2} - x_i}{2c}, \\
z_j &= \frac{\sqrt{x_j^2 + 4c^2} + x_j}{2c}, \\
K(z) &= -\frac{1}{2} \log^2 \frac{(z - z_-)(z_+ - z)}{(z_+ + z)(z_- + z)} - 2Li_2 \left( \frac{2z_-(z_+ - z)}{(z_+ - z_-)(z_- + z)} \right) \\
&\quad - 2Li_2 \left( -\frac{2z_+(z_- + z)}{(z_+ - z_-)(z_+ - z)} \right)
\end{aligned}$$

Massive-Massless Case

$$\mathcal{I}_{ij} = \frac{1}{2} \left[ \log^2 \frac{Q}{s} - \frac{\pi^2}{6} \right] - \frac{1}{2} I_0(k_i, k_j) \log \frac{Q^2}{s} - \frac{1}{2} I_\epsilon(k_i, k_j) \quad (26.6)$$

with

$$\begin{aligned}
I_0(p, k) &= \log \frac{(\hat{p} \cdot \hat{k})^2}{\hat{k}^2}, \\
I_\epsilon(p, k) &= -2 \left[ \frac{1}{4} \log^2 \frac{1-\beta}{1+\beta} + \log \frac{\hat{p} \cdot \hat{k}}{1+\beta} \log \frac{\hat{p} \cdot \hat{k}}{1-\beta} + Li_2 \left( 1 - \frac{\hat{p} \cdot \hat{k}}{1+\beta} \right) + Li_2 \left( 1 - \frac{\hat{p} \cdot \hat{k}}{1-\beta} \right) \right]
\end{aligned}$$

using

$$\hat{p} = \frac{p}{p^0}, \quad \hat{k} = \frac{k}{k^0}, \quad \beta = \frac{|\vec{k}|}{k_0}.$$

```

⟨real subtraction: parameters⟩≡
    integer, parameter, public :: INTEGRATION = 0
    integer, parameter, public :: FIXED_ORDER_EVENTS = 1
    integer, parameter, public :: POWHEG = 2

```

In the soft limit, the real matrix element behaves as

$$\mathcal{R}_{\text{soft}} = 4\pi\alpha_s \left[ \sum_{i \neq j} \mathcal{B}_{ij} \frac{k_i \cdot k_j}{(k_i \cdot k)(k_j \cdot k)} - \mathcal{B} \sum_i \frac{k_i^2}{(k_i \cdot k)^2} C_i \right],$$

where  $k$  denotes the momentum of the emitted parton. The quantity  $\mathcal{B}_{ij}$  is

called the color-correlated Born matrix element defined as

$$\mathcal{B}_{ij} = \frac{1}{2s} \sum_{\substack{\text{colors} \\ \text{spins}}} \mathcal{M}_{\{c_k\}} \left( \mathcal{M}_{\{c_k\}}^\dagger \right)_{\substack{c_i \rightarrow c'_i \\ c_j \rightarrow c'_j}} T_{c_i, c'_i}^a T_{c_j, c'_j}^a.$$

    allocate (sub_soft%momentum_matrix &
              (nlegs_born, nlegs_born))
  end subroutine soft_subtraction_init
```

The treatment of the momentum  $k$  follows the discussion about the soft limit of the partition functions (ref????). The parton momentum is pulled out,  $k = E\hat{k}$ . In fact, we will substitute  $\hat{k}$  for  $k$  throughout the code, because the energy will factor out of the equation when the soft  $\mathcal{S}$ -function is multiplied. The soft momentum is a unit vector, because  $k^2 = (k^0)^2 - (\vec{k})^2 = 0$ .

```
(real subtraction: procedures)+≡
  function create_softvec_fsr (p_born, y, phi, emitter) result (p_soft)
    type(vector4_t), intent(in), dimension(:) :: p_born
    real(default), intent(in) :: y, phi
    integer, intent(in) :: emitter
    type(vector4_t) :: p_soft
    type(vector3_t) :: dir
    type(lorentz_transformation_t) :: rot
```

The soft momentum is constructed by first creating a unit vector parallel to the emitter's Born momentum. This unit vector is then rotated about the corresponding angles  $y$  and  $\phi$ .

```
(real subtraction: procedures)+≡
```

```

p_soft%p(0) = 1._default

    type(pdf_container_t), pointer :: pdf_scaled_minus => null()
  contains
  ⟨real subtraction: coll sub: TBP⟩
end type coll_subtraction_t

⟨real subtraction: coll sub: TBP⟩≡
  procedure :: init => coll_subtraction_init

⟨real subtraction: procedures⟩+≡
  subroutine coll_subtraction_init (coll_sub, n_alr)
    class(coll_subtraction_t), intent(inout) :: coll_sub
    integer, intent(in) :: n_alr
    coll_sub%n_alr = n_alr
    allocate (coll_sub%value (n_alr))
    allocate (coll_sub%value_soft (n_alr))
  end subroutine coll_subtraction_init

```

To compute the collinear limit of  $\mathcal{R}$ , we follow the original FKS-paper. Here, the real amplitude is supposed to factorize in the collinear limit. considering a splitting  $g \rightarrow g(i)g(j)$ ,

$$\mathcal{A}^{(n)}(h_i, h_j, \{h_l\}) \xrightarrow{i||j} g_s \sum_{d_e} \sum_{h_e} C(d_e, b, c) S_{gg}^{h_e h_i h_j}(z) \mathcal{A}_{d_e}^{(n-1)}(h_e, \{h_l\})$$

**Explain quantities.** Evaluating this expression leads to

$$|\mathcal{A}^{(n)}(h_i, h_j, \{h_l\})|^2 \xrightarrow{i||j} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 + |\mathcal{R}(h_i, h_j, \{h_l\})|^2,$$

where  $\mathcal{R}$  contains all contributions with spin-correlated amplitudes, i.e. terms like  $\mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left( \mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^*$ . Explicitly,

$$\sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} |\mathcal{N}^{(n)}(h_i, h_j, \{h_l\})|^2 = \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) |\mathcal{A}^{(n-1)}|^2,$$

and

$$\begin{aligned} \sum_{h_i, h_j, \{h_l\}} \sum_{\{d_l\}} \mathcal{R}(h_i, h_j, \{h_l\}) &= 32\pi\alpha_s C_A z(1-z) \\ &\times \underbrace{\text{Re} \left\{ \frac{\langle ij \rangle}{[ij]} \sum_{\{h_l\}} \sum_{d_e, \{d_l\}} \mathcal{A}_{d_e}^{(n-1)}(+, \{h_l\}) \left( \mathcal{A}_{d_e}^{(n-1)}(-, \{h_l\}) \right)^* \right\}}_{-\tilde{\mathcal{M}}^{(n-1)} / (2k_i \cdot k_j)}. \end{aligned}$$

This yields

$$\mathcal{M}^{(n)} \xrightarrow{i \parallel j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{gg}(z) \mathcal{M}^{(n-1)} - \frac{16\pi\alpha_s}{k_i \cdot k_j} C_A z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (26.7)$$

The equivalent expression for a  $g \rightarrow qq$ -splitting is given by

$$\mathcal{M}^{(n)} \xrightarrow{i \parallel j} \frac{4\pi\alpha_s}{k_i \cdot k_j} P_{qg}(z) \mathcal{M}^{(n-1)} + \frac{16\pi\alpha_s}{k_i \cdot k_j} T_F z(1-z) \tilde{\mathcal{M}}^{(n-1)}. \quad (26.8)$$

```
(real subtraction: coll sub: TBP)+≡
procedure :: compute_fsr => coll_subtraction_compute_fsr

```

The function obtains a flag to indicate whether the limit to be computed is also soft. Moreover, this consideration explains the structure of the code. In the soft limit, we find  $z \rightarrow 0$  as well as  $\xi \rightarrow 0$ . However, the quantity  $z/\xi$  is finite, because

$$\frac{z}{\xi} = \frac{p_{rad}^0}{\bar{p}_{em}^0} \frac{q^0}{2p_{em}^0} = \frac{q^0}{2\bar{p}_{em}^0}.$$

Thus, all expressions are written in terms of this well-behaved quantity. Recalling that there is a prefactor of  $(\xi^2 z)^{-1}$ , it is necessary to expand with  $z$  once.

### 26.5.3 The real contribution to the cross section

In each singular region  $\alpha$ , the real contribution to  $\sigma$  is given by the second summand of eqn. ??,

$$\sigma_{\text{real}}^{\alpha} = \int d\Phi_n \int_0^{2\pi} d\phi \int_{-1}^1 dy \int_0^{\xi_{\max}} d\xi \left( \frac{1}{\xi} \right)_+ \left( \frac{1}{1-y} \right)_+ \underbrace{\frac{J(\Phi_n, \xi, y, \phi)}{\xi} [(1-y)\xi^2 \mathcal{R}^{\alpha}(\Phi_{n+1})]}_{g^{\alpha}(\xi, y)} . \quad (26.9)$$

Writing out the plus-distribution and introducing  $\tilde{\xi} = \xi/\xi_{\max}$  to set the upper integration limit to 1, this turns out to be equal to

$$\begin{aligned} \sigma_{\text{real}}^{\alpha} = & \int d\Phi_n \int_0^{2/p_i} d\phi \int_{-1}^1 \frac{dy}{1-y} \left\{ \int_0^1 d\tilde{\xi} \left[ \underbrace{\frac{g^{\alpha}(\tilde{\xi}\xi_{\max}, y)}{\tilde{\xi}}}_{\text{soft}} - \underbrace{\frac{g^{\alpha}(0, y)}{\tilde{\xi}}}_{\text{coll.}} - \underbrace{\frac{g^{\alpha}(\tilde{\xi}\xi_{\max}, 1)}{\tilde{\xi}}}_{\text{coll. + soft}} + \underbrace{\frac{g^{\alpha}(0, 1)}{\tilde{\xi}}}_{\text{coll. + soft}} \right] \right. \\ & \left. + [\log \xi_{\max}(y) g^{\alpha}(0, y) - \log \xi_{\max}(1) g^{\alpha}(0, 1)] \right\}. \end{aligned} \quad (26.10)$$

This formula is implemented in `compute_sqme_real_fin`

```
<real subtraction: real subtraction: TBP>+≡
procedure :: compute => real_subtraction_compute
<real subtraction: procedures>+≡
function real_subtraction_compute (rsub, emitter, i_flv, alpha_s) result (sqme)
  class(real_subtraction_t), intent(inout) :: rsub
  integer, intent(in) :: emitter, i_flv
  real(default) :: alpha_s
  real(default) :: sqme
  integer :: alr

  sqme = 0._default
  do alr = 1, size (rsub%reg_data%regions)
    if (emitter == rsub%reg_data%regions(alr)%emitter .and. &
        i_flv == rsub%reg_data%regions(alr)%real_index) then
      call rsub%set_alr (alr)
      if (emitter <= 2) then
        sqme = sqme + rsub%evaluate_region_isr (emitter, alpha_s)
      else
        sqme = sqme + rsub%evaluate_region_fsr (emitter, alpha_s)
      end if
    end if
  end do
  if (rsub%purpose == INTEGRATION .or. rsub%purpose == FIXED_ORDER_EVENTS) &
    sqme = sqme*rsub%get_phs_factor ()
end function real_subtraction_compute
```

This subroutine computes the finite part of the real matrix element in an individual singular region. First, the radiation variables are fetched and  $\mathcal{R}$  is multiplied by the appropriate  $S_{\alpha}$ -factors, region multiplicities and double-FSR

factors. Then, it computes the soft, collinear, soft-collinear and remnant matrix elements and supplies the corresponding factor  $1/\xi/(1-y)$  as well as the corresponding jacobians.

The fks phase space type contains the wood phase space and separately the in- and outcoming momenta for the real process and the corresponding Born momenta. Additionally, there are the variables  $\xi, \xi_{max}, y$  and  $\phi$  which are used to create the real phase space, as well as the jacobian and its corresponding soft and collinear limit. Lastly, the array `ch_to_em` connects each channel with an emitter.

### 26.7.1 Creation of the real phase space - FSR

At this point, the Born phase space has been generated, as well as the three random variables  $\xi$ ,  $y$  and  $\phi$ . The question is how the real phase space is generated for a final-state emission configuration. We work with two different sets of momenta, the Born configuration  $\{\bar{k}_\oplus, \bar{k}_\ominus, \bar{k}_1, \dots, \bar{k}_n\}$  and the real configuration  $\{k_\oplus, k_\ominus, k_1, \dots, k_n, k_{n+1}\}$ . We define the momentum of the emitter to be on the  $n$ -th position and the momentum of the radiated particle to be at position  $n+1$ . The magnitude of the spatial component of  $k$  is denoted by  $\underline{k}$ .

For final-state emissions, it is  $\bar{k}_\oplus = k_\oplus$  and  $\bar{k}_\ominus = k_\ominus$ . Thus, the center-of-mass systems coincide and it is

$$q = \sum_{i=1}^n \bar{k}_i = \sum_{i=1}^{n+1} k_i, \quad (26.11)$$

with  $\vec{q} = 0$  and  $q^2 = (q^0)^2$ .

We want to construct the real phase space from the Born phase space using three random numbers. They are defined as follows:

- $\xi = \frac{2k_{n+1}^0}{\sqrt{s}} \in [0, \xi_{max}]$ , where  $k_{n+1}$  denotes the four-momentum of the radiated particle.
- $y = \cos \theta = \frac{\bar{k}_n \cdot \bar{k}_{n+1}}{\underline{k}_n \underline{k}_{n+1}}$  is the splitting angle.
- The angle between the two splitting particles in the transversal plane,  $\text{phi} \in [0, 2\pi]$ .

Further,  $k_{rec} = \sum_{i=1}^{n-1} k_i$  denotes the sum of all recoiling momenta.

Construction of the recoiling momenta. The reshuffling of momenta must not change the invariant mass of the recoiling system, which means  $k_{\text{rec}}^2 = k_{\text{rec}}^{-2}$ .

Therefore, the momenta are related by a boost,  $\bar{k}_i = \Lambda k_i$ . The boost parameter is

$$\beta = \frac{q^2 - (k_{\text{rec}}^0 + \underline{k}_{\text{rec}})^2}{q^2 + (k_{\text{rec}}^0 + \underline{k}_{\text{rec}})^2}$$

```

```

The momentum of the radiated particle is computed according to

$$\underline{k}_n = \frac{q^2 - M_{\text{rec}}^2 - 2q^0 \underline{k}_{n+1}}{2(q^0 - \underline{k}_{n+1}(1-y))}, \quad (26.12)$$

with  $k = k_n + k_{n+1}$  and  $M_{\text{rec}}^2 = k_{\text{rec}}^2 = (q - k)^2$ . Because of  $\bar{\mathbf{k}}_n \parallel \mathbf{k}_n + \mathbf{k}_{n+1}$  we find  $M_{\text{rec}}^2 = (q - \bar{\mathbf{k}}_n)^2$ . Equation ?? follows from the fact that  $(\mathbf{k} - \mathbf{k}_n)^2 = \mathbf{k}_{n+1}^2$ , which is equivalent to  $\mathbf{k}_n \cdot \mathbf{k} = \frac{1}{2}(\mathbf{k}_n^2 + \mathbf{k}^2 - \mathbf{k}_{n+1}^2)$ .  $\mathbf{k}_n$  and  $\mathbf{k}_{n+1}$  are obtained by first setting up vectors parallel to  $\bar{\mathbf{k}}_n$ ,

$$\mathbf{k}'_n = \underline{k}_n \frac{\bar{\mathbf{k}}_n}{\underline{k}_n}, \quad \mathbf{k}'_{n+1} = \underline{k}_{n+1} \frac{\bar{\mathbf{k}}_n}{\underline{k}_n},$$

and then rotating these vectors by an amount of  $\cos \psi_n = \frac{\underline{k}_n \cdot \underline{k}}{\underline{k}_n \cdot \underline{k}}$ . The emitted particle cannot have more momentum than the emitter has in the Born phase space. Thus, there is an upper bound for  $\xi$ , determined by the condition  $k_{n+1}^0 = \underline{k}_n$ , which is equal to

$$\xi_{\max} = \frac{2}{\bar{k}_n} q^0.$$

```
<phs fks: procedures>+≡

    real(default) :: xi_max
    real(default) :: uk_n_born, q0
    q0 = p_born(1)%p(0) + p_born(2)%p(0)
    uk_n_born = space_part_norm (p_born(emitter))
    xi_max = 2*uk_n_born / q0
end function get_xi_max_fsr_massless
```

The computation of  $\xi_{\max}$  for massive emitters is described in arXiv:1202.0465. Let's recapitulate it here.

We consider the Dalitz-domain created by  $k_{n+1}^0$ ,  $k_n^0$  and  $k_{\text{rec}}^0$  and introduce the parameterization

$$k_n^0 = \bar{k}_n^0 - z k_{n+1}^0$$

Then, for each value of  $z$ , there exists a maximum value of  $\underline{k}_{n+1}$  from which  $\xi_{\max}$  can be extracted via  $\xi_{\max} = 2\underline{k}_{n+1}^0/q$ . It is determined by the condition

$$\underline{k}_{n+1} \pm \underline{k}_n \pm \underline{k}_{\text{rec}} = 0.$$

This can be manipulated to yield

$$(\underline{k}_{n+1}^2 + \underline{k}_n^2 - \underline{k}_{\text{rec}}^2)^2 = 4\underline{k}_{n+1}^2 \underline{k}_n^2.$$

Here we can use  $\underline{k}_n^2 = (k_n^0)^2 - m^2$  and  $\underline{k}_{\text{rec}}^2 = (q - k_n^0 - k_{n+1}^0)^2 - M_{\text{rec}}^2$ , as well as the above parameterization of  $k_n^0$ , to obtain

$$4\underline{k}_{n+1}^2 (2\underline{k}_{n+1} q z (1-z) + q^2 z^2 - 2q \bar{k}_{\text{rec}}^0 z + M_{\text{rec}}^2) = 0.$$

Solving for  $\underline{k}_{n+1}^0$  gives

$$k_{n+1}^0 = \frac{2q \bar{k}_{\text{rec}}^0 z - q^2 z^2 - M_{\text{rec}}^2}{2qz(1-z)}. \quad (26.13)$$

It is still open how to compute  $z$ . For this, consider that the right-hand-side of equation (26.13) vanishes for

$$z_{1,2} = \left( \bar{k}_{\text{rec}}^0 \pm \sqrt{(\bar{k}_{\text{rec}}^0)^2 - M_{\text{rec}}^2} \right) / q,$$

which corresponds to the borders of the Dalitz-region where the gluon momentum vanishes. Thus we define

$$z = z_2 - \frac{1}{2}(z_2 - z_1)(1+y).$$

```

## 26.8 Subtraction of initial-state divergences

We must calculate two terms,  $G_{\oplus}$  and  $G_{\ominus}$  for each possible initial-state emitter. Following the notation of 0709.2092, this is separated into  $G = \tilde{\mathcal{L}}\mathcal{G}$ , such that  $\tilde{\mathcal{L}}$  contains the PDF-values at the scales, explicitly

$$\tilde{\mathcal{L}} = \begin{cases} \mathcal{L}(\bar{x}_{\oplus}/z, \bar{x}_{\ominus}) & \text{for } \alpha \in \text{ISR}_{\oplus} \\ \mathcal{L}(\bar{x}_{\oplus}, \bar{x}_{\ominus}/z) & \text{for } \alpha \in \text{ISR}_{\ominus} \end{cases}$$

For each flavor combination  $f_{\oplus}$  and  $f_{\ominus}$  of initial-state particles, the relevant terms are given by

$$\mathcal{G}_{\oplus}^{f_{\oplus} f_{\ominus}}(z) = \frac{\alpha_s}{2\pi} \sum_{f'_{\oplus}} \left\{ (1-z) P^{f_{\oplus} f'_{\ominus}}(z, 0) \left[ \left( \frac{1}{1-z} \right)_+ \log \frac{s}{2\mu_F^2} + 2 \left( \frac{\log(1-z)}{1-z} \right)_+ \right] - \left[ \frac{\partial P^{f_{\oplus} f'_{\ominus}}(z, \epsilon)}{\partial \epsilon} \right]_{\epsilon=0} - K^{f_{\oplus} f'_{\ominus}} \right\} \mathcal{B}^{f'_{\oplus} f_{\ominus}}(z)$$

where  $P(z, \epsilon)$  are the Altarelli-Parisi splitting functions

$$\begin{aligned} P_{qq}(z, \epsilon) &= C_F \left[ \frac{1+z^2}{1-z} - \epsilon(1-z) \right], \\ P_{qg}(z, \epsilon) &= C_F \left[ \frac{1+(1-z)^2}{z} - \epsilon z \right], \\ P_{gg}(z, \epsilon) &= T_F \left[ 1 - \frac{2z(1-z)}{1-\epsilon} \right], \\ P_{gg}(z, \epsilon) &= 2C_A \left[ \frac{z}{1-z} + \frac{1-z}{z} + z(1-z) \right]. \end{aligned}$$

In the code we deal with  $\hat{P}^{f_{\oplus} f_{\ominus}}(z) = (1-z)P^{f_{\oplus} f_{\ominus}}(z, 0)$  because this quantity behaves nicely in the limit  $z \rightarrow 1$ . The factor  $K^{f_{\oplus} f_{\ominus}}$  depends on the renormalization scheme and vanishes for  $\overline{MS}$ .

The second thing to consider is the fact that the integration over  $z$  is carried out over the interval  $[\bar{x}_{\oplus}, 1]$  or  $[\bar{x}_{\ominus}, 1]$ , respectively, but the plus-distribution can only be evaluated over  $[0, 1]$ . We thus use the identities

$$\begin{aligned} \int_{\bar{x}_{\oplus}}^1 dz \left( \frac{1}{1-z} \right)_+ f(z) &= \log(1 - \bar{x}_{\oplus}) f(1) + \int_{\bar{x}_{\oplus}}^1 dz \frac{f(z) - f(1)}{1-z}, \\ \int_{\bar{x}_{\oplus}}^1 dz \left( \frac{\log(1-z)}{1-z} \right)_+ f(z) &= \frac{1}{2} \log^2(1 - \bar{x}_{\oplus}) f(1) + \int_{\bar{x}_{\oplus}}^1 dz \frac{\log(1-z)[f(z) - f(1)]}{1-z}. \end{aligned}$$

## Chapter 27

# Model Handling and Features

These modules deal with process definitions and physics models.

These modules use the `model_data` methods to automatically generate process definitions.

**auto\_components** Generic process-definition generator. We can specify a basic process or initial particle(s) and some rules to extend this process, given a model definition with particle names and vertex structures.

**radiation\_generator** Applies the generic generator to the specific problem of generating NLO corrections in a restricted setup.

Model construction:

**eval\_trees** Implementation of the generic `expr_t` type for the concrete evaluation of expressions that access user variables.

This module is actually part of the Sindarin language implementation, and should be moved elsewhere. Currently, the `models` module relies on it.

**models** Extends the `model_data_t` structure by user-variable objects for easy access, and provides the means to read a model definition from file.

**slha\_interface** Read/write a SUSY model in the standardized SLHA format. The format defines fields and parameters, but no vertices.

## 27.1 Automatic generation of process components

This module provides the functionality for automatically generating radiation corrections or decays, provided as lists of PDG codes.

```
⟨auto_components.f90⟩≡
  ⟨File header⟩

  module auto_components

    ⟨Use kinds⟩
    ⟨Use strings⟩
      use io_units
      use diagnostics
      use model_data
      use pdg_arrays

    ⟨Auto components: public⟩

    ⟨Auto components: types⟩

    ⟨Auto components: interfaces⟩

    contains

    ⟨Auto components: procedures⟩

  end module auto_components
```

### 27.1.1 Constraints: Abstract types

An abstract type that denotes a constraint on the automatically generated states. The concrete objects are applied as visitor objects at certain hooks during the splitting algorithm.

```
⟨Auto components: types⟩≡
  type, abstract :: split_constraint_t
  contains
    ⟨Auto components: split constraint: TBP⟩
  end type split_constraint_t
```

By default, all checks return true.

```
⟨Auto components: split constraint: TBP⟩≡
  procedure :: check_before_split => split_constraint_check_before_split
  procedure :: check_before_insert => split_constraint_check_before_insert
  procedure :: check_before_record => split_constraint_check_before_record

  ⟨Auto components: procedures⟩≡
    subroutine split_constraint_check_before_split (c, table, pl, k, passed)
      class(split_constraint_t), intent(in) :: c
      class(ps_table_t), intent(in) :: table
```

```

type(pdg_list_t), intent(in) :: pl
integer, intent(in) :: k
logical, intent(out) :: passed
passed = .true.
end subroutine split_constraint_check_before_split

subroutine split_constraint_check_before_insert (c, table, pa, pl, passed)
  class(split_constraint_t), intent(in) :: c
  class(ps_table_t), intent(in) :: table
  type(pdg_array_t), intent(in) :: pa
  type(pdg_list_t), intent(inout) :: pl
  logical, intent(out) :: passed
  passed = .true.
end subroutine split_constraint_check_before_insert

subroutine split_constraint_check_before_record (c, table, pl, n_loop, passed)
  class(split_constraint_t), intent(in) :: c
  class(ps_table_t), intent(in) :: table
  type(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_loop
  logical, intent(out) :: passed
  passed = .true.
end subroutine split_constraint_check_before_record

```

A transparent wrapper, so we can collect constraints of different type.

*(Auto components: types)*+≡

```

type :: split_constraint_wrap_t
  class(split_constraint_t), allocatable :: c
end type split_constraint_wrap_t

```

A collection of constraints.

*(Auto components: public)*≡

```

public :: split_constraints_t

```

*(Auto components: types)*+≡

```

type :: split_constraints_t
  class(split_constraint_wrap_t), dimension(:), allocatable :: cc
contains
  (Auto components: split constraints: TBP)
end type split_constraints_t

```

Initialize the constraints set with a specific number of elements.

*(Auto components: split constraints: TBP)*≡

```

procedure :: init => split_constraints_init

```

*(Auto components: procedures)*+≡

```

subroutine split_constraints_init (constraints, n)
  class(split_constraints_t), intent(out) :: constraints
  integer, intent(in) :: n
  allocate (constraints%cc (n))
end subroutine split_constraints_init

```

Set a constraint.

```
<Auto components: split constraints: TBP>+≡
    procedure :: set => split_constraints_set
<Auto components: procedures>+≡
    subroutine split_constraints_set (constraints, i, c)
        class(split_constraints_t), intent(inout) :: constraints
        integer, intent(in) :: i
        class(split_constraint_t), intent(in) :: c
        allocate (constraints%cc(i)%c, source = c)
    end subroutine split_constraints_set
```

Apply checks.

`check_before_split` is applied to the particle list that we want to split.  
`check_before_insert` is applied to the particle list `pl` that is to replace the particle `pa` that is split. This check may transform the particle list.

`check_before_record` is applied to the complete new particle list that results from splitting before it is recorded.

```
<Auto components: split constraints: TBP>+≡
    procedure :: check_before_split => split_constraints_check_before_split
    procedure :: check_before_insert => split_constraints_check_before_insert
    procedure :: check_before_record => split_constraints_check_before_record

end subroutine split_constraints_check_before_record

```

### 27.1.2 Specific constraints

#### Number of particles

Specific constraint: The number of particles plus the number of loops, if any, must remain less than the given limit. Note that the number of loops is defined only when we are recording the entry.

```

<Auto components: types>+≡
    type, extends (split_constraint_t) :: constraint_n_tot
        private
        integer :: n_max = 0
    contains
        procedure :: check_before_split => constraint_n_tot_check_before_split
        procedure :: check_before_record => constraint_n_tot_check_before_record
    end type constraint_n_tot

<Auto components: public>+≡
    public :: constrain_n_tot

<Auto components: procedures>+≡
    function constrain_n_tot (n_max) result (c)
        integer, intent(in) :: n_max
        type(constraint_n_tot) :: c
        c%n_max = n_max
    end function constrain_n_tot

    subroutine constraint_n_tot_check_before_split (c, table, pl, k, passed)
        class(constraint_n_tot), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: k
        logical, intent(out) :: passed
        passed = pl%get_size () < c%n_max
    end subroutine constraint_n_tot_check_before_split

    subroutine constraint_n_tot_check_before_record (c, table, pl, n_loop, passed)
        class(constraint_n_tot), intent(in) :: c
        class(ps_table_t), intent(in) :: table

```

```

type(pdg_list_t), intent(in) :: pl
integer, intent(in) :: n_loop
logical, intent(out) :: passed
passed = pl%get_size () + n_loop <= c%n_max
end subroutine constraint_n_tot_check_before_record

```

### Number of loops

Specific constraint: The number of loops is limited, independent of the total number of particles.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_n_loop
    private
    integer :: n_loop_max = 0
  contains
    procedure :: check_before_record => constraint_n_loop_check_before_record
  end type constraint_n_loop

<Auto components: public>+≡
  public :: constrain_n_loop

<Auto components: procedures>+≡
  function constrain_n_loop (n_loop_max) result (c)
    integer, intent(in) :: n_loop_max
    type(constraint_n_loop) :: c
    c%n_loop_max = n_loop_max
  end function constrain_n_loop

  subroutine constraint_n_loop_check_before_record &
    (c, table, pl, n_loop, passed)
    class(constraint_n_loop), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_list_t), intent(in) :: pl
    integer, intent(in) :: n_loop
    logical, intent(out) :: passed
    passed = n_loop <= c%n_loop_max
  end subroutine constraint_n_loop_check_before_record

```

### Particles allowed in splitting

Specific constraint: The entries in the particle list ready for insertion are matched to a given list of particle patterns. If a match occurs, the entry is replaced by the corresponding pattern. If there is no match, the check fails.

```

<Auto components: types>+≡
  type, extends (split_constraint_t) :: constraint_insert
    private
    type(pdg_list_t) :: pl_match
  contains
    procedure :: check_before_insert => constraint_insert_check_before_insert
  end type constraint_insert

```

```

⟨Auto components: public⟩+≡
    public :: constrain_insert

⟨Auto components: procedures⟩+≡
    function constrain_insert (pl_match) result (c)
        type(pdg_list_t), intent(in) :: pl_match
        type(constraint_insert) :: c
        c%pl_match = pl_match
    end function constrain_insert

    subroutine constraint_insert_check_before_insert (c, table, pa, pl, passed)
        class(constraint_insert), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_array_t), intent(in) :: pa
        type(pdg_list_t), intent(inout) :: pl
        logical, intent(out) :: passed
        call pl%match_replace (c%pl_match, passed)
    end subroutine constraint_insert_check_before_insert

```

### Particles required in final state

Specific constraint: The entries in the recorded state must be a superset of the entries in the given list (for instance, the lowest-order state).

```

⟨Auto components: types⟩+≡
    type, extends (split_constraint_t) :: constraint_require
        private
        type(pdg_list_t) :: pl
        contains
            procedure :: check_before_record => constraint_require_check_before_record
    end type constraint_require

```

We check the current state by matching all particle entries against the stored particle list, and crossing out the particles in the latter list when a match is found. The constraint passed if all entries have been crossed out.

For an `if_table` in particular, we check the final state only.

```

⟨Auto components: public⟩+≡
    public :: constrain_require

⟨Auto components: procedures⟩+≡
    function constrain_require (pl) result (c)
        type(pdg_list_t), intent(in) :: pl
        type(constraint_require) :: c
        c%pl = pl
    end function constrain_require

    subroutine constraint_require_check_before_record &
        (c, table, pl, n_loop, passed)
        class(constraint_require), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        logical, dimension(:), allocatable :: mask

```

```

integer :: i, k, n_in
select type (table)
type is (if_table_t)
    n_in = 2
class default
    n_in = 0
end select
allocate (mask (c%pl%get_size (), source = .true.))
do i = n_in + 1, pl%get_size ()
    k = c%pl%find_match (pl%get (i), mask)
    if (k /= 0)  mask(k) = .false.
end do
passed = .not. any (mask)
end subroutine constraint_require_check_before_record

```

## Radiation

Specific constraint: We have radiation pattern if the original particle matches an entry in the list of particles that should replace it. The constraint prohibits this situation.

```

⟨Auto components: public⟩+≡
public :: constrain_radiation

⟨Auto components: types⟩+≡
type, extends (split_constraint_t) :: constraint_radiation
private
contains
procedure :: check_before_insert => &
    constraint_radiation_check_before_insert
end type constraint_radiation

⟨Auto components: procedures⟩+≡
function constrain_radiation () result (c)
    type(constraint_radiation) :: c
end function constrain_radiation

subroutine constraint_radiation_check_before_insert (c, table, pa, pl, passed)
    class(constraint_radiation), intent(in) :: c
    class(ps_table_t), intent(in) :: table
    type(pdg_array_t), intent(in) :: pa
    type(pdg_list_t), intent(inout) :: pl
    logical, intent(out) :: passed
    passed = .not. (pl .match. pa)
end subroutine constraint_radiation_check_before_insert

```

## Mass sum

Specific constraint: The sum of masses within the particle list must be smaller than a given limit. For in/out state combinations, we check initial and final state separately.

If we specify `margin` in the initialization, the sum must be strictly less than the limit minus the given margin (which may be zero). If not, equality is allowed.

```

⟨Auto components: public⟩+≡
    public :: constrain_mass_sum

⟨Auto components: types⟩+≡
    type, extends (split_constraint_t) :: constraint_mass_sum
        private
        real(default) :: mass_limit = 0
        logical :: strictly_less = .false.
        real(default) :: margin = 0
        contains
            procedure :: check_before_record => constraint_mass_sum_check_before_record
    end type constraint_mass_sum

⟨Auto components: procedures⟩+≡
    function constrain_mass_sum (mass_limit, margin) result (c)
        real(default), intent(in) :: mass_limit
        real(default), intent(in), optional :: margin
        type(constraint_mass_sum) :: c
        c%mass_limit = mass_limit
        if (present (margin)) then
            c%strictly_less = .true.
            c%margin = margin
        end if
    end function constrain_mass_sum

    subroutine constraint_mass_sum_check_before_record &
        (c, table, pl, n_loop, passed)
        class(constraint_mass_sum), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        real(default) :: limit
        if (c%strictly_less) then
            limit = c%mass_limit - c%margin
            select type (table)
                type is (if_table_t)
                    passed = mass_sum (pl, 1, 2, table%model) < limit &
                        .and. mass_sum (pl, 3, pl%get_size (), table%model) < limit
                class default
                    passed = mass_sum (pl, 1, pl%get_size (), table%model) < limit
                end select
            else
                limit = c%mass_limit
                select type (table)
                    type is (if_table_t)
                        passed = mass_sum (pl, 1, 2, table%model) <= limit &
                            .and. mass_sum (pl, 3, pl%get_size (), table%model) <= limit
                class default
                    passed = mass_sum (pl, 1, pl%get_size (), table%model) <= limit
                end select
            end if
        end if
    end subroutine constraint_mass_sum_check_before_record

```

```
end subroutine constraint_mass_sum_check_before_record
```

### Initial state particles

Specific constraint: The two incoming particles must both match the given particle list. This is checked for the generated particle list, just before it is recorded.

```
(Auto components: public)+≡
    public :: constrain_in_state

(Auto components: types)+≡
    type, extends (split_constraint_t) :: constraint_in_state
        private
        type(pdg_list_t) :: pl
        contains
            procedure :: check_before_record => constraint_in_state_check_before_record
    end type constraint_in_state

(Auto components: procedures)+≡
    function constrain_in_state (pl) result (c)
        type(pdg_list_t), intent(in) :: pl
        type(constraint_in_state) :: c
        c%pl = pl
    end function constrain_in_state

    subroutine constraint_in_state_check_before_record &
        (c, table, pl, n_loop, passed)
        class(constraint_in_state), intent(in) :: c
        class(ps_table_t), intent(in) :: table
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_loop
        logical, intent(out) :: passed
        integer :: i
        select type (table)
        type is (if_table_t)
            passed = .false.
            do i = 1, 2
                if (.not. (c%pl .match. pl%get (i))) return
            end do
        end select
        passed = .true.
    end subroutine constraint_in_state_check_before_record
```

### 27.1.3 Tables of states

Automatically generate a list of possible process components for a given initial set (a single massive particle or a preset list of states).

The set of process components are generated by recursive splitting, applying constraints on the fly that control and limit the process. The generated states are accumulated in a table that we can read out after completion.

```
(Auto components: types)+≡
```

```

type, extends (pdg_list_t) :: ps_entry_t
    integer :: n_loop = 0
    integer :: n_rad = 0
    type(ps_entry_t), pointer :: previous => null ()
    type(ps_entry_t), pointer :: next => null ()
end type ps_entry_t

```

This is the wrapper type for the decay tree for the list of final states and the final array. First, an abstract base type:

```

⟨Auto components: public⟩+≡
public :: ps_table_t

⟨Auto components: types⟩+≡
type, abstract :: ps_table_t
private
class(model_data_t), pointer :: model => null ()
logical :: loops = .false.
type(ps_entry_t), pointer :: first => null ()
type(ps_entry_t), pointer :: last => null ()
contains
⟨Auto components: ps table: TBP⟩
end type ps_table_t

```

The extensions: one for decay, one for generic final states. The decay-state table stores the initial particle. The final-state table is indifferent, and the initial/final state table treats the first two particles in its list as incoming antiparticles.

```

⟨Auto components: public⟩+≡
public :: ds_table_t
public :: fs_table_t
public :: if_table_t

⟨Auto components: types⟩+≡
type, extends (ps_table_t) :: ds_table_t
private
integer :: pdg_in = 0
contains
⟨Auto components: ds table: TBP⟩
end type ds_table_t

type, extends (ps_table_t) :: fs_table_t
contains
⟨Auto components: fs table: TBP⟩
end type fs_table_t

type, extends (fs_table_t) :: if_table_t
contains
⟨Auto components: if table: TBP⟩
end type if_table_t

```

Finalizer: we must deallocate the embedded list.

```

⟨Auto components: ps table: TBP⟩≡
procedure :: final => ps_table_final

```

```

⟨Auto components: procedures⟩+≡
    subroutine ps_table_final (object)
        class(ps_table_t), intent(inout) :: object
        type(ps_entry_t), pointer :: current
        do while (associated (object%first))
            current => object%first
            object%first => current%next
            deallocate (current)
        end do
        nullify (object%last)
    end subroutine ps_table_final

```

Write the table. A base writer for the body and specific writers for the headers.

```

⟨Auto components: ps table: TBP⟩+≡
    procedure :: base_write => ps_table_base_write
    procedure (ps_table_write), deferred :: write

⟨Auto components: interfaces⟩≡
    interface
        subroutine ps_table_write (object, unit)
            import
            class(ps_table_t), intent(in) :: object
            integer, intent(in), optional :: unit
        end subroutine ps_table_write
    end interface

⟨Auto components: ds table: TBP⟩≡
    procedure :: write => ds_table_write

⟨Auto components: fs table: TBP⟩≡
    procedure :: write => fs_table_write

⟨Auto components: if table: TBP⟩≡
    procedure :: write => if_table_write

```

The first `n_in` particles will be replaced by antiparticles in the output, and we write an arrow if `n_in` is present.

```

⟨Auto components: procedures⟩+≡
    subroutine ps_table_base_write (object, unit, n_in)
        class(ps_table_t), intent(in) :: object
        integer, intent(in), optional :: unit

  table%loops = .true.
end subroutine ps_table_enable_loops

```

#### 27.1.4 Top-level methods

Create a table for a single-particle decay. Construct all possible final states from a single particle with PDG code `pdg_in`. The construction is limited by the given `constraints`.

```

⟨Auto components: ds table: TBP⟩+≡
procedure :: make => ds_table_make
⟨Auto components: procedures⟩+≡
subroutine ds_table_make (table, model, pdg_in, constraints)
  class(ds_table_t), intent(out) :: table
  class(model_data_t), intent(in), target :: model
  integer, intent(in) :: pdg_in
  type(split_constraints_t), intent(in) :: constraints
  type(pdg_list_t) :: pl_in
  type(pdg_list_t), dimension(0) :: pl
  call table%init (model, pl, constraints)
  table%pdg_in = pdg_in
  call pl_in%init (1)
  call pl_in%set (1, [pdg_in])
  call table%split (pl_in, 0, constraints)
end subroutine ds_table_make

```

Split all entries in a growing table, starting from a table that may already contain states. Add and record split states on the fly.

```

⟨Auto components: fs table: TBP⟩+≡
procedure :: radiate => fs_table_radiate
⟨Auto components: procedures⟩+≡
subroutine fs_table_radiate (table, constraints)
  class(fs_table_t), intent(inout) :: table
  type(split_constraints_t) :: constraints
  type(ps_entry_t), pointer :: current
  current => table%first
  do while (associated (current))
    call table%split (current, 0, constraints, record = .true.)
    current => current%next
  end do
end subroutine fs_table_radiate

```

### 27.1.5 Splitting algorithm

Recursive splitting. First of all, we record the current `pdg_list` in the table, subject to `constraints`, if requested. We also record copies of the list marked as loop corrections.

When we record a particle list, we sort it first.

If there is room for splitting, We take a PDG array list and the index of an element, and split this element in all possible ways. The split entry is inserted into the list, which we split further.

The recursion terminates whenever the split array would have a length greater than  $n_{\max}$ .

```

<Auto components: ps table: TBP>+≡
    procedure :: split => ps_table_split

<Auto components: procedures>+≡
    recursive subroutine ps_table_split (table, pl, n_rad, constraints, &
                                         record)
        class(ps_table_t), intent(inout) :: table
        class(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n_rad
        type(split_constraints_t), intent(in) :: constraints
        logical, intent(in), optional :: record
        integer :: n_loop, i
        logical :: passed
        type(vertex_iterator_t) :: vit
        integer, dimension(:), allocatable :: pdg1
        integer, dimension(:), allocatable :: pdg2
        if (present (record)) then
            if (record) then
                n_loop = 0
                INCR_LOOPS: do
                    call table%record_sorted (pl, n_loop, n_rad, constraints, passed)
                    if (.not. passed) exit INCR_LOOPS
                    if (.not. table%loops) exit INCR_LOOPS
                    n_loop = n_loop + 1
                end do INCR_LOOPS
            end if
        end if
        do i = 1, pl%get_size ()
            call constraints%check_before_split (table, pl, i, passed)
            if (passed) then
                pdg1 = pl%get (i)
                call vit%init (table%model, pdg1)
                SCAN_VERTICES: do
                    call vit%get_next_match (pdg2)
                    if (allocated (pdg2)) then
                        call table%insert (pl, n_rad, i, pdg2, constraints)
                    else
                        exit SCAN_VERTICES
                    end if
                end do SCAN_VERTICES
            end if
        end do
    end subroutine ps_table_split

```

The worker part: insert the list of particles found by vertex matching in place of entry *i* in the PDG list. Then split/record further.

The *n\_in* parameter tells the replacement routine to insert the new particles after entry *n\_in*. Otherwise, they follow index *i*.

```
<Auto components: ps table: TBP>+≡
procedure :: insert => ps_table_insert
<Auto components: procedures>+≡
recursive subroutine ps_table_insert &
  (table, pl, n_rad, i, pdg, constraints, n_in)
  class(ps_table_t), intent(inout) :: table
  class(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_rad, i
  integer, dimension(:,), intent(in) :: pdg
  type(split_constraints_t), intent(in) :: constraints
  integer, intent(in), optional :: n_in
  type(pdg_list_t) :: pl_insert
  logical :: passed
  integer :: k, s
  s = size (pdg)
  call pl_insert%init (s)
  do k = 1, s
    call pl_insert%set (k, pdg(k))
  end do
  call constraints%check_before_insert (table, pl%get (i), pl_insert, passed)
  if (passed) then
    call table%split (pl%replace (i, pl_insert, n_in), n_rad + s - 1, &
      constraints, record = .true.)
  end if
end subroutine ps_table_insert
```

Special case: If we are splitting an initial particle, there is slightly more to do. We loop over the particles from the vertex match and replace the initial particle by each of them in turn. The remaining particles must be appended after the second initial particle, so they will end up in the out state. This is done by providing the *n\_in* argument to the base method as an optional argument.

Note that we must call the base-method procedure explicitly, so the *table* argument keeps its dynamic type as *if\_table* inside this procedure.

```
<Auto components: if table: TBP>+≡
procedure :: insert => if_table_insert
<Auto components: procedures>+≡
recursive subroutine if_table_insert &
  (table, pl, n_rad, i, pdg, constraints, n_in)
  class(if_table_t), intent(inout) :: table
  class(pdg_list_t), intent(in) :: pl
  integer, intent(in) :: n_rad, i
  integer, dimension(:,), intent(in) :: pdg
  type(split_constraints_t), intent(in) :: constraints
  integer, intent(in), optional :: n_in
  integer, dimension(:,), allocatable :: pdg_work
  integer :: p
```

```

if (i > 2) then
    call ps_table_insert (table, pl, n_rad, i, pdg, constraints)
else
    allocate (pdg_work (size (pdg)))
    do p = 1, size (pdg)
        pdg_work(1) = pdg(p)
        pdg_work(2:p) = pdg(1:p-1)
        pdg_work(p+1:) = pdg(p+1:)
        call ps_table_insert (table, &
            pl, n_rad, i, pdg_work, constraints, n_in = 2)
    end do
end if
end subroutine if_table_insert

```

Sort before recording. In the case of the `if_table`, we do not sort the first `n_in` particle entries. Instead, we check whether they are allowed in the `pl_beam` PDG list, if that is provided.

```

⟨Auto components: ps table: TBP⟩+≡
    procedure :: record_sorted => ps_table_record_sorted
⟨Auto components: if table: TBP⟩+≡
    procedure :: record_sorted => if_table_record_sorted

```

### 27.1.6 Tools

Compute the mass sum for a PDG list object, counting the entries with indices between (including) `n1` and `n2`. Rely on the requirement that if an entry is a PDG array, this array must be degenerate in mass.

```

⟨Auto components: procedures⟩+≡
    function mass_sum (pl, n1, n2, model) result (m)
        type(pdg_list_t), intent(in) :: pl
        integer, intent(in) :: n1, n2
        class(model_data_t), intent(in), target :: model
        integer, dimension(:), allocatable :: pdg
        real(default) :: m
        type(field_data_t), pointer :: prt
        integer :: i
        m = 0
        do i = n1, n2
            pdg = pl%get (i)
            prt => model%get_field_ptr (pdg(1))
            m = m + prt%get_mass ()
        end do
    end function mass_sum

```

Invert a PDG array, replacing particles by antiparticles. This depends on the model.

```

⟨Auto components: procedures⟩+≡
    function invert_pdg_array (pa, model) result (pa_inv)
        type(pdg_array_t), intent(in) :: pa
        class(model_data_t), intent(in), target :: model
        type(pdg_array_t) :: pa_inv
        type(field_data_t), pointer :: prt
        integer :: i, pdg
        pa_inv = pa
        do i = 1, pa_inv%get_length ()
            pdg = pa_inv%get (i)
            prt => model%get_field_ptr (pdg)
            if (prt%has_antiparticle ()) call pa_inv%set (i, -pdg)
        end do
    end function invert_pdg_array

```

### 27.1.7 Access results

Return the number of generated decays.

```

⟨Auto components: ps table: TBP⟩+≡

## 27.3 Sindarin Expression Implementation

This module defines expressions of all kinds, represented in a tree structure, for repeated evaluation. This provides an implementation of the `expr_base` abstract type.

We have two flavors of expressions: one with particles and one without particles. The latter version is used for defining cut/selection criteria and for online analysis.

```

### 27.3.1 Tree nodes

The evaluation tree consists of branch nodes (unary and binary) and of leaf nodes, originating from a common root. The node object should be polymorphic. For the time being, polymorphism is emulated here. This means that we have to maintain all possibilities that the node may hold, including associated procedures as pointers.

The following parameter values characterize the node. Unary and binary operators have sub-nodes. The other are leaf nodes. Possible leafs are literal constants or named-parameter references.

*(Eval trees: types)*≡

```
integer, parameter :: EN_UNKNOWN = 0, EN_UNARY = 1, EN_BINARY = 2
integer, parameter :: EN_CONSTANT = 3, EN_VARIABLE = 4
integer, parameter :: EN_CONDITIONAL = 5, EN_BLOCK = 6
integer, parameter :: EN_RECORD_CMD = 7
integer, parameter :: EN_OBS1_INT = 11, EN_OBS2_INT = 12
integer, parameter :: EN_OBS1_REAL = 21, EN_OBS2_REAL = 22
integer, parameter :: EN_UOBS1_INT = 31, EN_UOBS2_INT = 32
integer, parameter :: EN_UOBS1_REAL = 41, EN_UOBS2_REAL = 42
integer, parameter :: EN_PRT_FUN_UNARY = 101, EN_PRT_FUN_BINARY = 102
integer, parameter :: EN_EVAL_FUN_UNARY = 111, EN_EVAL_FUN_BINARY = 112
integer, parameter :: EN_LOG_FUN_UNARY = 121, EN_LOG_FUN_BINARY = 122
integer, parameter :: EN_INT_FUN_UNARY = 131, EN_INT_FUN_BINARY = 132
integer, parameter :: EN_REAL_FUN_UNARY = 141, EN_REAL_FUN_BINARY = 142
integer, parameter :: EN_FORMAT_STR = 161
```

This is exported only for use within unit tests.

        case (V_STR); allocate (node%sval)
    end select
    allocate (node%value_is_known)
    node%value_is_known = .false.
end subroutine eval_node_allocate_value

```

Initialize a block node which contains, in addition to the expression to be evaluated, a variable definition. The result type is not yet assigned, because we can compile the enclosed expression only after the var list is set up.

Note that the node always allocates a new variable list and appends it to the current one. Thus, if the variable redefines an existing one, it only shadows it but does not reset it. Any side-effects are therefore absent and need not be undone outside the block.

If the flag **new** is set, a variable is (re)declared. This must not be done for intrinsic variables. Vice versa, if the variable is not existent, the **new** flag is required.

*(Eval trees: procedures)*+≡

```

subroutine eval_node_init_block (node, name, type, var_def, var_list)
    type(eval_node_t), intent(out), target :: node
    type(string_t), intent(in) :: name
    integer, intent(in) :: type
    type(eval_node_t), intent(in), target :: var_def

end if
end subroutine eval_node_init_block

```

Complete block initialization by assigning the expression to evaluate to `arg0`.

*(Eval trees: procedures)*+≡

```

subroutine eval_node_set_expr (node, arg, result_type)
    type(eval_node_t), intent(inout) :: node
    type(eval_node_t), intent(in), target :: arg
    integer, intent(in), optional :: result_type
    if (present (result_type)) then
        node%result_type = result_type
    else
        node%result_type = arg%result_type

```

```

    end if
    call eval_node_allocate_value (node)
    node%arg0 => arg
end subroutine eval_node_set_expr

```

Initialize a conditional. There are three branches: the condition (evaluates to logical) and the two alternatives (evaluate both to the same arbitrary type).

```

⟨Eval trees: procedures⟩+≡
subroutine eval_node_init_conditional (node, result_type, cond, arg1, arg2)
    type(eval_node_t), intent(out) :: node
    integer, intent(in) :: result_type
    type(eval_node_t), intent(in), target :: cond, arg1, arg2
    node%type = EN_CONDITIONAL
    node%tag = "cond"
    node%result_type = result_type
    call eval_node_allocate_value (node)
    node%arg0 => cond
    node%arg1 => arg1
    node%arg2 => arg2
end subroutine eval_node_init_conditional

```

Initialize a recording command (which evaluates to a logical constant). The first branch is the ID of the analysis object to be filled, the optional branches 1 to 4 are the values to be recorded.

If the event-weight pointer is null, we record values with unit weight. Otherwise, we use the value pointed to as event weight.

There can be up to four arguments which represent  $x, y, \Delta y, \Delta x$ . Therefore, this is the only node type that may fill four sub-nodes.

```

⟨Eval trees: procedures⟩+≡
subroutine eval_node_init_record_cmd &
    (node, event_weight, id, arg1, arg2, arg3, arg4)
    type(eval_node_t), intent(out) :: node
    real(default), pointer :: event_weight
    type(eval_node_t), intent(in), target :: id
    type(eval_node_t), intent(in), optional, target :: arg1, arg2, arg3, arg4
    call eval_node_init_log (node, .true.)
    node%type = EN_RECORD_CMD
    node%rval => event_weight
    node%tag = "record_cmd"
    node%arg0 => id
    if (present (arg1)) then
        node%arg1 => arg1
        if (present (arg2)) then
            node%arg2 => arg2
            if (present (arg3)) then
                node%arg3 => arg3
                if (present (arg4)) then
                    node%arg4 => arg4
                end if
            end if
        end if
    end if
end if

```

```
end subroutine eval_node_init_record_cmd
```

Initialize a node for operations on subevents. The particle lists (one or two) are inserted as `arg1` and `arg2`. We allocated particle pointers as temporaries for iterating over particle lists. The procedure pointer which holds the function to evaluate for the subevents (e.g., combine, select) is also initialized.

*(Eval trees: procedures)*+≡

```
subroutine eval_node_init_prt_fun_unary (node, arg1, name, proc)
    type(eval_node_t), intent(out) :: node
    type(eval_node_t), intent(in), target :: arg1
    type(string_t), intent(in) :: name
    procedure(unary_sev) :: proc
    node%type = EN_PRT_FUN_UNARY
    node%tag = name
    node%result_type = V_SEV
    call eval_node_allocate_value (node)
    node%arg1 => arg1
    allocate (node%index, source = 0)

end subroutine eval_node_init_real_fun_binary

```

Initialize a node for a string formatting function (sprintf).

*(Eval trees: procedures)*+≡

```

subroutine eval_node_init_format_string (node, fmt, arg, name, n_args)
  type(eval_node_t), intent(out) :: node
  type(eval_node_t), pointer :: fmt, arg
  type(string_t), intent(in) :: name
  integer, intent(in) :: n_args
  node%type = EN_FORMAT_STR
  node%tag = name
  node%result_type = V_STR
  call eval_node_allocate_value (node)
  node%arg0 => fmt
  node%arg1 => arg
  allocate (node%ival)
  node%ival = n_args
end subroutine eval_node_init_format_string

```

If particle functions depend upon a condition (or an expression is evaluated), the observables that can be evaluated for the given particles have to be thrown on the local variable stack. This is done here. Each observable is initialized with the particle pointers which have been allocated for the node.

The integer variable that is referred to by the `Index` pseudo-observable is always known when it is referred to.

*(Eval trees: procedures)*+≡

```

subroutine eval_node_set_observables (node, var_list)
  type(eval_node_t), intent(inout) :: node
  type(var_list_t), intent(in), target :: var_list
  logical, save, target :: known = .true.
  allocate (node%var_list)
  call node%var_list%link (var_list)
  allocate (node%index, source = 0)
  call var_list_append_int_ptr &
    (node%var_list, var_str ("Index"), node%index, known, intrinsic=.true.)
  if (.not. associated (node%prt2)) then
    call var_list_set_observables_unary &
      (node%var_list, node%prt1)
  else
    call var_list_set_observables_binary &
      (node%var_list, node%prt1, node%prt2)
  end if
end subroutine eval_node_set_observables

```

### 27.3.2 Operation types

For the operations associated to evaluation tree nodes, we define abstract interfaces for all cases.

Particles/subevents are transferred by-reference, to avoid unnecessary copying. Therefore, subroutines instead of functions. (Furthermore, the function version of `unary_prt` triggers an obscure bug in nagfor 5.2(649) [invalid C code].)

```

<Eval trees: interfaces>≡
abstract interface
    logical function unary_log (arg)
        import eval_node_t

```

```

        type(eval_node_t), intent(in) :: arg
    end function unary_log
end interface
abstract interface
    integer function unary_int (arg)
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_int
end interface
abstract interface
    real(function unary_real (arg)
        import default
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_real
end interface
abstract interface
    complex(function unary_cmplx (arg)
        import default
        import eval_node_t
        type(eval_node_t), intent(in) :: arg
    end function unary_cmplx
end interface
abstract interface
    subroutine unary_pdg (pdg_array, arg)
        import pdg_array_t
        import eval_node_t
        type(pdg_array_t), intent(out) :: pdg_array
        type(eval_node_t), intent(in) :: arg
    end subroutine unary_pdg

### 27.3.3 Specific operators

Our expression syntax contains all Fortran functions that make sense. These functions have to be provided in a form that they can be used in procedures pointers, and have the abstract interfaces above. For some intrinsic functions, we could use specific versions provided by Fortran directly. However, this has two drawbacks: (i) We should work with the values instead of the eval-nodes as argument, which complicates the interface; (ii) more importantly, the `default` real type need not be equivalent to double precision. This would, at least, introduce system dependencies. Finally, for operators there are no specific versions.

Therefore, we write wrappers for all possible functions, at the expense of some overhead.

#### Binary numerical functions

```

⟨Eval trees: procedures⟩+≡
integer function add_ii (en1, en2) result (y)
type(eval_node_t), intent(in) :: en1, en2
y = en1%ival + en2%ival
end function add_ii
real(default) function add_ir (en1, en2) result (y)
type(eval_node_t), intent(in) :: en1, en2
y = en1%ival + en2%rval
end function add_ir
complex(default) function add_ic (en1, en2) result (y)
type(eval_node_t), intent(in) :: en1, en2
y = en1%ival + en2%cval
end function add_ic
real(default) function add_ri (en1, en2) result (y)
type(eval_node_t), intent(in) :: en1, en2
y = en1%rval + en2%ival
end function add_ri
complex(default) function add_ci (en1, en2) result (y)
type(eval_node_t), intent(in) :: en1, en2
y = en1%cval + en2%ival
end function add_ci

```

```

end function no_p

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

```

        int (subevt_get_length (en1%pval), kind=c_int))
end subroutine user_event_shape_a

```

### Binary particle-list functions

This joins two subevents, stored in the evaluation nodes `en1` and `en2`. If `en0` is also present, it amounts to a logical test returning true or false for every pair of particles. A particle of the second list gets a mask entry only if it passes the test for all particles of the first list.

```

<Eval trees: procedures>+≡
subroutine join_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask2
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask2 (n2))
    mask2 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subevt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask2(j) = mask2(j) .and. en0%lval
            end do
        end do
    end if
end subroutine join_pp

```

```

        end do
    end do
end if
call subevt_join (subevt, en1%pval, en2%pval, mask2)
end subroutine join_pp

```

Combine two subevents, i.e., make a list of composite particles built from all possible particle pairs from the two lists. If `en0` is present, create a mask which is true only for those pairs that pass the test.

*(Eval trees: procedures) +≡*

```

subroutine combine_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:, :, ), allocatable :: mask12
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    if (present (en0)) then
        allocate (mask12 (n1, n2))
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)
            do j = 1, n2
                en0%prt2 = subevt_get_prt (en2%pval, j)
                call eval_node_evaluate (en0)
                mask12(i,j) = en0%lval
            end do
        end do
        call subevt_combine (subevt, en1%pval, en2%pval, mask12)
    else
        call subevt_combine (subevt, en1%pval, en2%pval)
    end if
end subroutine combine_pp

```

Combine all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored.

*(Eval trees: procedures) +≡*

```

subroutine collect_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:, ), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask1 (n1))
    mask1 = .true.
    if (present (en0)) then
        do i = 1, n1
            en0%index = i
            en0%prt1 = subevt_get_prt (en1%pval, i)

```

```

        do j = 1, n2
            en0%prt2 = subevt_get_prt (en2%pval, j)
            call eval_node_evaluate (en0)
            mask1(i) = mask1(i) .and. en0%lval
        end do
    end do
end if
call subevt_collect (subevt, en1%pval, mask1)
end subroutine collect_pp

```

Select all particles of the first argument. If `en0` is present, create a mask which is true only for those particles that pass the test w.r.t. all particles in the second argument. If `en0` is absent, the second argument is ignored, and the first argument is transferred unchanged. (This case is not very useful, of course.)

*(Eval trees: procedures)*+≡

```

subroutine select_pp (subevt, en1, en2, en0)
    type(subevt_t), intent(inout) :: subevt
    type(eval_node_t), intent(in) :: en1, en2
    type(eval_node_t), intent(inout), optional :: en0
    logical, dimension(:), allocatable :: mask1
    integer :: i, j, n1, n2
    n1 = subevt_get_length (en1%pval)
    n2 = subevt_get_length (en2%pval)
    allocate (mask1 (n1))
    mask1 = .true.
    if (present (en0)) then
        do i = 1, n1

            exit LOOP1
        end if
    end do
end do LOOP1
end subroutine eval_pp

```

This is the interface to user-supplied observables. The node `en0` evaluates to a string that indicates the procedure name. We search for the procedure in the dynamic library and load it into the procedure pointer which is then called. `en1` is the subevent on which the external code operates. The external function returns a `c_int`, which we translate into a real value.

```

<Eval trees: procedures>+≡
function user_obs_int_pp (en0, prt1, prt2) result (ival)
    integer :: ival
    type(eval_node_t), intent(inout) :: en0

```

The following function returns an integer value, namely the number of valid particle-pairs from both lists for which the condition is true. Invalid pairs (with common `src` entry) are ignored. If there is no condition, it returns the number of valid particle pairs.

A function would be more natural. Making it a subroutine avoids another compiler bug (internal error in nagfor 5.2 (649)). (See the interface `binary_num.`)

```

<Eval trees: procedures>+≡
subroutine count_pp (ival, en1, en2, en0)
    integer, intent(out) :: ival

  else
    call subevt_select_pdg_code (subevt, en1%aval, en2%pval)
  end if
end subroutine select_pdg_ca
```

### Binary string functions

Currently, the only string operation is concatenation.

*(Eval trees: procedures)*+≡

```
subroutine concat_ss (string, en1, en2)
  type(string_t), intent(out) :: string
  type(eval_node_t), intent(in) :: en1, en2
  string = en1%sval // en2%sval
end subroutine concat_ss
```

#### 27.3.4 Compiling the parse tree

The evaluation tree is built recursively by following a parse tree. Evaluate an expression. The requested type is given as an optional argument; default is numeric (integer or real).

*(Eval trees: procedures)*+≡

```
recursive subroutine eval_node_compile_genexpr &
  (en, pn, var_list, result_type)
  type(eval_node_t), pointer :: en
  type(parse_node_t), intent(in) :: pn
  type(var_list_t), intent(in), target :: var_list
  integer, intent(in), optional :: result_type
  if (debug_active (D_MODEL_F)) then
    print *, "read genexpr"; call parse_node_write (pn)
  end if
  if (present (result_type)) then
    select case (result_type)
    case (V_INT, V_REAL, V_CMPLX)
      call eval_node_compile_expr (en, pn, var_list)
    case (V_LOG)
      call eval_node_compile_lexpr (en, pn, var_list)
    case (V_SEV)
      call eval_node_compile_pexpr (en, pn, var_list)
    case (V_PDG)
```

```

        call eval_node_compile_cexpr (en, pn, var_list)
case (V_STR)
    call eval_node_compile_sexpr (en, pn, var_list)
end select
else
    call eval_node_compile_expr  (en, pn, var_list)
end if
if (debug_active (D_MODEL_F)) then
    call eval_node_write (en)
    print *, "done genexpr"
end if
end subroutine eval_node_compile_genexpr

```

## Numeric expressions

This procedure compiles a numerical expression. This is a single term or a sum or difference of terms. We have to account for all combinations of integer and real arguments. If both are constant, we immediately do the calculation and allocate a constant node.

```

⟨Eval trees: procedures⟩+≡

```

Real, complex and integer values are numeric literals with an optional unit attached. In case of an integer, the unit actually makes it a real value in disguise. The signed version of real values is not possible in generic expressions; it is a special case for numeric constants in model files (see below). We do not introduce signed versions of complex values.

```

Compile a variable, with or without a specified type. Take the list of variables, look for the name and make a node with a pointer to the value. If no type is provided, the variable is numeric, and the stored value determines whether it is real or integer.

We explicitly demand that the variable is defined, so we do not accidentally point to variables that are declared only later in the script but have come into existence in a previous compilation pass.

Variables may actually be anonymous, these are expressions in disguise. In that case, the expression replaces the variable name in the parse tree, and we allocate an ordinary expression node in the eval tree.

Variables of type V\_PDG (pdg-code array) are not treated here. They are handled by eval\_node\_compile\_cvariable.

Retrieve the result of an integration. If the requested process has been integrated, the results are available as special variables. (The variables cannot be accessed in the usual way since they contain brackets in their names.)

Since this compilation step may occur before the processes have been loaded, we have to initialize the required variables before they are used.

```

This user observable behaves like a variable. We link the node to the generic user-observable entry in the variable list. The syntax element has an argument which provides the name of the user variable, this is stored as an eval-node alongside with the variable. When the variable value is used, the user-supplied external function is called and provides the (real) result value.

## Variable definition

A block expression contains a variable definition (first argument) and an expression where the definition can be used (second argument). The `result_type` decides which type of expression is expected for the second argument. For numeric variables, if there is a mismatch between real and integer type, insert an extra node for type conversion.

```

## Conditionals

A conditional has the structure if lexpr then expr else expr. So we first evaluate the logical expression, then depending on the result the first or second expression. Note that the second expression is mandatory.

The `result_type`, if present, defines the requested type of the `then` and `else` clauses. Default is numeric (int/real). If there is a mismatch between real and integer result types, insert conversion nodes.

```

## Comparisons

Up to the loop, this is easy. There is always at least one comparison. This is evaluated, and the result is the logical node `en`. If it is constant, we keep its second sub-node as `en2`. (Thus, at the very end `en2` has to be deleted if `en` is (still) constant.)

If there is another comparison, we first check if the first comparison was constant. In that case, there are two possibilities: (i) it was true. Then, its right-hand side is compared with the new right-hand side, and the result replaces the previous one which is deleted. (ii) it was false. In this case, the result of the whole comparison is false, and we can exit the loop without evaluating anything else.

Now assume that the first comparison results in a valid branch, its second sub-node kept as `en2`. We first need a copy of this, which becomes the new left-hand side. If `en2` is constant, we make an identical constant node `en1`. Otherwise, we make `en1` an appropriate pointer node. Next, the first branch is saved as `en0` and we evaluate the comparison between `en1` and the a right-hand side. If this turns out to be constant, there are again two possibilities: (i) true, then we revert to the previous result. (ii) false, then the wh

```

end if
end subroutine eval_node_compile_compared_expr

```

This takes two extra arguments: `en1`, the left-hand-side of the comparison, is already allocated and evaluated. `en2` (the right-hand side) and `en` (the result)

are allocated by the routine. `pn` is the parse node which contains the operator and the right-hand side as subnodes.

If the result of the comparison is constant, `en1` is deleted but `en2` is kept, because it may be used in a subsequent comparison. `en` then becomes a constant. If the result is variable, `en` becomes a branch node which refers to `en1` and `en2`.

        call eval_node_write (en)
        print *, "done pterm"
    end if
end subroutine eval_node_compile_pterm

```

A particle-list value is a PDG-code array, a particle identifier, a variable, a (grouped) pexpr, a block pexpr, a conditional, or a particle-list function.

The `cexpr` node is responsible for transforming a constant PDG-code array into a subevent. It takes the code array as its first argument, the event subevent as its second argument, and the requested particle type (incoming/outgoing) as its zero-th argument. The result is the list of particles in the event that match the code array.

```

## Particle functions

This combines the treatment of 'join', 'combine', 'collect', 'cluster', 'select', and 'extract' which all have the same syntax. The one or two argument nodes are allocated. If there is a condition, the condition node is also allocated as a logical expression, for which the variable list is augmented by the appropriate (unary/binary) observables.

*(Eval trees: procedures)* +≡

```

### PDG-code arrays

A PDG-code expression is either prefixed by `incoming` or `outgoing`, a block, or a conditional. In any case, it evaluates to a constant.

*(Eval trees: procedures)* +≡

```

recursive subroutine eval_node_compile_prefix_cexpr (en, pn, var_list)
    type(eval_node_t), pointer :: en
    type(parse_node_t), intent(in) :: pn
    type(var_list_t), intent(in), target :: var_list
    type(parse_node_t), pointer :: pn_avelue, pn_ptr
    type(string_t) :: key
    if (debug_active (D_MODEL_F)) then
        print *, "read prefix_cexpr";  call parse_node_write (pn)
    end if
    pn_avelue => parse_node_get_sub_ptr (pn)
    key = parse_node_get_rule_key (pn_avelue)
    select case (char (key))
    case ("incoming_ptr")
        pn_ptr => parse_node_get_sub_ptr (pn_avelue, 2)

```

```

    call eval_node_compile_cexpr (en, pn_prt, var_list)
case ("outgoing_ptr")
    pn_prt => parse_node_get_sub_ptr (pn_avelue, 1)
    call eval_node_compile_cexpr (en, pn_prt, var_list)

```

### 27.3.5 Auxiliary functions for the compiler

Issue an error that the current node could not be compiled because of type mismatch:

```

<Eval trees: procedures>+≡
subroutine eval_type_error (pn, string, t)
    type(parse_node_t), intent(in) :: pn
    character(*), intent(in) :: string
    integer, intent(in) :: t
    type(string_t) :: type
    select case (t)
    case (V_NONE); type = "(none)"
    case (V_LOG); type = "'logical'"
    case (V_INT); type = "'integer'"
    case (V_REAL); type = "'real'"
    case (V_CMPLX); type = "'complex'"
    case default; type = "(unknown)"
    end select
    call parse_node_write (pn)
    call msg_fatal (" The " // string // &
                    " operation is not defined for the given argument type " // &
                    char (type))
end subroutine eval_type_error

```

If two numerics are combined, the result is integer if both arguments are integer, if one is integer and the other real or both are real, than its argument is real, otherwise complex.

```

<Eval trees: procedures>+≡
function numeric_result_type (t1, t2) result (t)
    integer, intent(in) :: t1, t2
    integer :: t
    if (t1 == V_INT .and. t2 == V_INT) then
        t = V_INT
    else if (t1 == V_INT .and. t2 == V_REAL) then
        t = V_REAL
    else if (t1 == V_REAL .and. t2 == V_INT) then
        t = V_REAL
    else if (t1 == V_REAL .and. t2 == V_REAL) then
        t = V_REAL
    else
        t = V_CMPLX
    end if

```

```
end function numeric_result_type
```

### 27.3.6 Evaluation

Evaluation is done recursively. For leaf nodes nothing is to be done.

Evaluating particle-list functions: First, we evaluate the particle lists. If a condition is present, we assign the particle pointers of the condition node to the allocated particle entries in the parent node, keeping in mind that the observables in the variable stack used for the evaluation of the condition also contain pointers to these entries. Then, the assigned procedure is evaluated, which sets the subevent in the parent node. If required, the procedure evaluates the condition node once for each (pair of) particles to determine the result.

```
(Eval trees: procedures)+≡
recursive subroutine eval_node_evaluate (en)
  type(eval_node_t), intent(inout) :: en
  logical :: exist
  select case (en%type)
  case (EN_UNARY)

### Test method

This is called from a unit test: initialize a particular observable.

```

⟨Eval trees: eval node: TBP⟩+≡
procedure :: test_obs => eval_node_test_obs
⟨Eval trees: procedures⟩+≡
subroutine eval_node_test_obs (node, var_list, var_name)
    class(eval_node_t), intent(inout) :: node
    type(var_list_t), intent(in) :: var_list
    type(string_t), intent(in) :: var_name
    procedure(obs_unary_int), pointer :: obs1_iptr
    type(prt_t), pointer :: p1
    call var_list%get_obs1_iptr (var_name, obs1_iptr, p1)
    call eval_node_init_obs1_int_ptr (node, var_name, obs1_iptr, p1)
end subroutine eval_node_test_obs

```

### 27.3.7 Evaluation syntax

We have two different flavors of the syntax: with and without particles.

```

⟨Eval trees: public⟩+≡
public :: syntax_expr
public :: syntax_pexpr
⟨Eval trees: variables⟩≡
type(syntax_t), target, save :: syntax_expr
type(syntax_t), target, save :: syntax_pexpr

```

These are for testing only and may be removed:

```

⟨Eval trees: public⟩+≡
public :: syntax_expr_init
public :: syntax_pexpr_init
⟨Eval trees: procedures⟩+≡
subroutine syntax_expr_init ()
    type(ifile_t) :: ifile
    call define_expr_syntax (ifile, particles=.false., analysis=.false.)
    call syntax_init (syntax_expr, ifile)
    call ifile_final (ifile)
end subroutine syntax_expr_init

subroutine syntax_pexpr_init ()

```

```

type(ifile_t) :: ifile
call define_expr_syntax (ifile, particles=.true., analysis=.false.)
call syntax_init (syntax_pexpr, ifile)
call ifile_final (ifile)
end subroutine syntax_pexpr_init

⟨Eval trees: public⟩+≡
public :: syntax_expr_final
public :: syntax_pexpr_final

⟨Eval trees: procedures⟩+≡
subroutine syntax_expr_final ()
    call syntax_final (syntax_expr)
end subroutine syntax_expr_final

subroutine syntax_pexpr_final ()
    call syntax_final (syntax_pexpr)
end subroutine syntax_pexpr_final

⟨Eval trees: public⟩+≡
public :: syntax_pexpr_write

⟨Eval trees: procedures⟩+≡
subroutine syntax_pexpr_write (unit)
    integer, intent(in), optional :: unit
    call syntax_write (syntax_pexpr, unit)
end subroutine syntax_pexpr_write

⟨Eval trees: public⟩+≡
public :: define_expr_syntax

Numeric expressions.

⟨Eval trees: procedures⟩+≡
subroutine define_expr_syntax (ifile, particles, analysis)
    type(ifile_t), intent(inout) :: ifile

if (present (result_type)) &
    result_type = eval_tree_get_result_type (eval_tree)
call eval_tree_final (eval_tree)
end subroutine eval_numeric

```

Error message with debugging info:

```

⟨Eval trees: procedures⟩+≡
subroutine eval_tree_unknown (eval_tree, parse_node)
    type(eval_tree_t), intent(in) :: eval_tree
    type(parse_node_t), intent(in) :: parse_node
    call parse_node_write_rec (parse_node)
    call eval_tree_write (eval_tree)
    call msg_error ("Evaluation yields an undefined result, inserting default")
end subroutine eval_tree_unknown

```

### 27.3.11 Factory Type

Since eval\_tree\_t is an implementation of expr\_t, we also need a matching factory type and build method.

```

⟨Eval trees: public⟩+≡
public :: eval_tree_factory_t

⟨Eval trees: types⟩+≡
type, extends (expr_factory_t) :: eval_tree_factory_t
    private
    type(parse_node_t), pointer :: pn => null ()
contains
⟨Eval trees: eval tree factory: TBP⟩

```

```
end type eval_tree_factory_t
```

Output: delegate to the output of the embedded parse node.

```
<Eval trees: eval tree factory: TBP>≡
procedure :: write => eval_tree_factory_write
<Eval trees: procedures>+≡
subroutine eval_tree_factory_write (expr_factory, unit)
  class(eval_tree_factory_t), intent(in) :: expr_factory
  integer, intent(in), optional :: unit
  if (associated (expr_factory%pn)) then
    call parse_node_write_rec (expr_factory%pn, unit)
  end if
end subroutine eval_tree_factory_write
```

Initializer: take a parse node and hide it thus from the environment.

```
<Eval trees: eval tree factory: TBP>+≡
procedure :: init => eval_tree_factory_init
<Eval trees: procedures>+≡
subroutine eval_tree_factory_init (expr_factory, pn)
  class(eval_tree_factory_t), intent(out) :: expr_factory
  type(parse_node_t), intent(in), pointer :: pn
  expr_factory%pn => pn
end subroutine eval_tree_factory_init
```

Factory method: allocate expression with correct eval tree type. If the stored parse node is not associate, don't allocate.

```
<Eval trees: eval tree factory: TBP>+≡
procedure :: build => eval_tree_factory_build
<Eval trees: procedures>+≡
subroutine eval_tree_factory_build (expr_factory, expr)
  class(eval_tree_factory_t), intent(in) :: expr_factory
  class(expr_t), intent(out), allocatable :: expr
  if (associated (expr_factory%pn)) then
    allocate (eval_tree_t :: expr)
    select type (expr)
    type is (eval_tree_t)
      expr%pn => expr_factory%pn
    end select
  end if
end subroutine eval_tree_factory_build
```

## 27.4 Physics Models

A model object represents a physics model. It contains a table of particle data, a list of parameters, and a vertex table. The list of parameters is a variable list which includes the real parameters (which are pointers to the particle data table) and PDG array variables for the particles themselves. The vertex list is used for phase-space generation, not for calculating the matrix element.

The actual numeric model data are in the base type `model_data_t`, as part of the `qft` section. We implement the `model_t` as an extension of this, for convenient direct access to the base-type methods via inheritance. (Alternatively, we could delegate these calls explicitly.) The extension contains administrative additions, such as the methods for recalculating derived data and keeping the parameter set consistent. It thus acts as a proxy of the actual model-data object towards the `WHIZARD` package. There are further proxy objects, such as the `parameter_t` array which provides the interface to the actual numeric parameters.

Model definitions are read from model files. Therefore, this module contains a parser for model files. The parameter definitions (derived parameters) are Sindarin expressions.

The models, as read from file, are stored in a model library which is a simple list of model definitions. For setting up a process object we should make a copy (an instance) of a model, which gets the current parameter values from the global variable list.

```

```
end module models
```

### 27.4.2 Physics Parameters

A parameter has a name, a value. Derived parameters also have a definition in terms of other parameters, which is stored as an `eval_tree`. External parameters are set by an external program.

This parameter object should be considered as a proxy object. The parameter name and value are stored in a corresponding `modelpar_data_t` object which is located in a `model_data_t` object. The latter is a component of the `model_t` handler. Methods of `parameter_t` can be delegated to the `par_data_t` component.

The `pn` component is a pointer to the parameter definition inside the model parse tree. It allows us to recreate the `eval_tree` when making copies (instances) of the parameter object.

```
(Models: parameters)≡
```

```
integer, parameter :: PAR_NONE = 0
integer, parameter :: PAR_INDEPENDENT = 1, PAR_DERIVED = 2
integer, parameter :: PAR_EXTERNAL = 3
```

```
(Models: types)≡
```

```
type :: parameter_t
  private
    integer :: type = PAR_NONE
    class(modelpar_data_t), pointer :: data => null()
    type(parse_node_t), pointer :: pn => null()
    class(expr_t), allocatable :: expr
contains
(Models: parameter: TBP)
end type parameter_t
```

Initialization depends on parameter type. Independent parameters are initialized by a constant value or a constant numerical expression (which may contain a unit). Derived parameters are initialized by an arbitrary numerical expression,

which makes use of the current variable list. The expression is evaluated by the function `parameter_reset`.

This implementation supports only real parameters and real values.

```
(Models: parameter: TBP)≡
procedure :: init_independent_value => parameter_init_independent_value
procedure :: init_independent => parameter_init_independent
procedure :: init_derived => parameter_init_derived
procedure :: init_external => parameter_init_external

(Models: procedures)≡
subroutine parameter_init_independent_value (par, par_data, name, value)
  class(parameter_t), intent(out) :: par

```

### 27.4.3 Model Object

A model object holds all information about parameters, particles, and vertices. For models that require an external program for parameter calculation, there is the pointer to a function that does this calculation, given the set of independent and derived parameters.

As explained above, the type inherits from `model_data_t`, which is the actual storage for the model data.

When reading a model, we create a parse tree. Parameter definitions are available via parse nodes. Since we may need those later when making model instances, we keep the whole parse tree in the model definition (but not in the instances).

```

⟨Models: public⟩≡
public :: model_t
⟨Models: types⟩+≡
type, extends (model_data_t) :: model_t
private
character(32) :: md5sum = ""
type(parameter_t), dimension(:), allocatable :: par

```

```

integer :: max_par_name_length = 0
integer :: max_field_name_length = 0
type(var_list_t) :: var_list
type(string_t) :: dlname
procedure(model_init_external_parameters), nopass, pointer :: &
    init_external_parameters => null ()
type(dlaccess_t) :: dlaccess
type(parse_tree_t) :: parse_tree
contains
<Models: model: TBP>
end type model_t

```

This is the interface for a procedure that initializes the calculation of external parameters, given the array of all parameters.

```

<Models: interfaces>≡
abstract interface
    subroutine model_init_external_parameters (par) bind (C)
        import
        real(c_default_float), dimension(*), intent(inout) :: par
    end subroutine model_init_external_parameters
end interface

```

Initialization: Specify the number of parameters, particles, vertices and allocate memory. If an associated DL library is specified, load this library.

```

<Models: model: TBP>≡
generic :: init => model_init
procedure, private :: model_init
<Models: procedures>+≡

        return
    end if
    call c_f_procpointer (c_fptr, model% init_external_parameters)
end if
end if
end subroutine model_init

```

For a model instance, we do not attempt to load a DL library. This is the core of the full initializer above.

```

⟨Models: model: TBP⟩+≡
procedure, private :: basic_init => model_basic_init
⟨Models: procedures⟩+≡
subroutine model_basic_init (model, name, n_par, n_prt, n_vtx)
    class(model_t), intent(inout) :: model
    type(string_t), intent(in) :: name
    integer, intent(in) :: n_par, n_prt, n_vtx
    allocate (model%par (n_par))
    call model%model_data_t%init (name, n_par, 0, n_prt, n_vtx)
end subroutine model_basic_init

```

Finalization: The variable list contains allocated pointers, also the parse tree. We also close the DL access object, if any, that enables external parameter calculation.

```

⟨Models: model: TBP⟩+≡
procedure :: final => model_final
⟨Models: procedures⟩+≡
subroutine model_final (model)
    class(model_t), intent(inout) :: model
    integer :: i
    if (allocated (model%par)) then
        do i = 1, size (model%par)
            call model%par(i)%final ()
        end do
    end if
    call model%var_list%final (follow_link=.false.)

```

```

if (model%dlname /= "")  call dlaccess_final (model%dlaccess)
call parse_tree_final (model%parse_tree)
call model%model_data_t%final ()
end subroutine model_final

```

Output. By default, the output is in the form of an input file. If verbose is true, for each derived parameter the definition (eval tree) is displayed, and the vertex hash table is shown.

```

#### 27.4.4 Model Access via Variables

Write the model variable list.

```

⟨Models: model: TBP⟩+≡
procedure :: write_var_list => model_write_var_list
⟨Models: procedures⟩+≡
subroutine model_write_var_list (model, unit, follow_link)
    class(model_t), intent(in) :: model
    integer, intent(in), optional :: unit
    logical, intent(in), optional :: follow_link
    call var_list_write (model%var_list, unit, follow_link)

```

```
    end subroutine model_write_var_list
```

Link a variable list to the model variables.

```
<Models: model: TBP>+≡  
    procedure :: link_var_list => model_link_var_list  
(Models: procedures)+≡  
    subroutine model_link_var_list (model, var_list)  
        class(model_t), intent(inout) :: model  
        type(var_list_t), intent(in), target :: var_list  
        call model%var_list%link (var_list)  
    end subroutine model_link_var_list
```

Check if the model contains a named variable.

```
<Models: model: TBP>+≡  
    procedure :: var_exists => model_var_exists  
(Models: procedures)+≡  
    function model_var_exists (model, name) result (flag)  
        class(model_t), intent(in) :: model  
        type(string_t), intent(in) :: name  
        logical :: flag  
        flag = model%var_list%contains (name, follow_link=.false.)  
    end function model_var_exists
```

Check if the model variable is a derived parameter, i.e., locked.

```
<Models: model: TBP>+≡  
    procedure :: var_is_locked => model_var_is_locked  
(Models: procedures)+≡  
    function model_var_is_locked (model, name) result (flag)  
        class(model_t), intent(in) :: model  
        type(string_t), intent(in) :: name  
        logical :: flag  
        flag = model%var_list%is_locked (name, follow_link=.false.)  
    end function model_var_is_locked
```

Set a model parameter via the named variable. We assume that the variable exists and is writable, i.e., non-locked. We update the model and variable list, so independent and derived parameters are always synchronized.

```
<Models: model: TBP>+≡  
    procedure :: set_real => model_var_set_real  
(Models: procedures)+≡  
    subroutine model_var_set_real (model, name, rval, verbose, pacified)  
        class(model_t), intent(inout) :: model  
        type(string_t), intent(in) :: name

#### 27.4.6 Model list

List of currently active models

*(Models: types)*+≡

```

type, extends (model_t) :: model_entry_t
    type(model_entry_t), pointer :: next => null ()
end type model_entry_t

(Models: public)+≡
public :: model_list_t

(Models: types)+≡
type :: model_list_t
    type(model_entry_t), pointer :: first => null ()
    type(model_entry_t), pointer :: last => null ()
    type(model_list_t), pointer :: context => null ()
contains
(Models: model list: TBP)

```

```
end type model_list_t
```

Write an account of the model list. We write linked lists first, starting from the global context.

```
(Models: model list: TBP)≡
procedure :: write => model_list_write
(Models: procedures)+≡
recursive subroutine model_list_write (object, unit, verbose, follow_link)
  class(model_list_t), intent(in) :: object
  integer, intent(in), optional :: unit
  logical, intent(in), optional :: verbose
  logical, intent(in), optional :: follow_link
  type(model_entry_t), pointer :: current
  logical :: rec
  integer :: u
  u = given_output_unit (unit); if (u < 0) return
  rec = .true.; if (present (follow_link)) rec = follow_link
  if (rec .and. associated (object%context)) then

  end if
  current => object%first
  if (associated (current)) then
    do while (associated (current))
      call current%write (unit, verbose)
      current => current%next
      if (associated (current)) write (u, *)
    end do
  end if
end subroutine model_list_write
```

Link this list to another one.

```
(Models: model list: TBP)+≡
procedure :: link => model_list_link
(Models: procedures)+≡
subroutine model_list_link (model_list, context)
  class(model_list_t), intent(inout) :: model_list
  type(model_list_t), intent(in), target :: context
  model_list%context => context
end subroutine model_list_link
```

(Private, used below:) Append an existing model, for which we have allocated a pointer entry, to the model list. The original pointer becomes disassociated, and the model should now be considered as part of the list. We assume that this model is not yet part of the list.

If we provide a `model` argument, this returns a pointer to the new entry.

```
(Models: model list: TBP)+≡
procedure, private :: import => model_list_import
(Models: procedures)+≡
subroutine model_list_import (model_list, current, model)
  class(model_list_t), intent(inout) :: model_list
```

```

type(model_entry_t), pointer, intent(inout) :: current
type(model_t), optional, pointer, intent(out) :: model
if (associated (current)) then
    if (associated (model_list%first)) then
        model_list%last%next => current
    else
        model_list%first => current
    end if
    model_list%last => current
    if (present (model))  model => current%model_t
    current => null ()
end if
end subroutine model_list_import

```

Currently test only:

Add a new model with given `name` to the list, if it does not yet exist. If successful, return a pointer to the new model.

```

⟨Models: model list: TBP⟩+≡
procedure :: add => model_list_add
⟨Models: procedures⟩+≡
subroutine model_list_add (model_list, &
    name, os_data, n_par, n_prt, n_vtx, model)
    class(model_list_t), intent(inout) :: model_list
    type(string_t), intent(in) :: name
    type(os_data_t), intent(in) :: os_data
    integer, intent(in) :: n_par, n_prt, n_vtx
    type(model_t), pointer :: model
    type(model_entry_t), pointer :: current
    if (model_list%model_exists (name, follow_link=.false.)) then
        model => null ()
    else
        allocate (current)
        call current%init (name, var_str (""), os_data, &
            n_par, n_prt, n_vtx)
        call model_list%import (current, model)
    end if
end subroutine model_list_add

```

Read a new model from file and add to the list, if it does not yet exist. Finalize the model by allocating the vertex table. Return a pointer to the new model. If unsuccessful, return the original pointer.

The model is always inserted in the last link of a chain of model lists. This way, we avoid loading models twice from different contexts. When a model is modified, we should first allocate a local copy.

```

⟨Models: model list: TBP⟩+≡
procedure :: read_model => model_list_read_model
⟨Models: procedures⟩+≡
subroutine model_list_read_model (model_list, name, filename, os_data, model)

end subroutine model_list_final

```

#### 27.4.7 Model instances

A model instance is a copy of a model object. The parameters are true copies. The particle data and the variable list pointers should point to the copy, so modifying the parameters has only a local effect. Hence, we build them up explicitly. The vertex array is also rebuilt, it contains particle pointers. Finally, the vertex hash table can be copied directly since it contains no pointers.

The `multiplicity` entry depends on the association of the `mass_data` entry and therefore has to be set at the end.

The instance must carry the `target` attribute.

Parameters: the `copy_parameter` method essentially copies the parameter decorations (parse node, expression etc.). The current parameter values are part of the `model_data_t` base type and are copied afterwards via its `copy_from` method.

```

<Models: model: TBP>+≡
procedure :: init_instance => model_copy

<Models: procedures>+≡
subroutine model_copy (model, orig)
class(model_t), intent(out), target :: model
type(model_t), intent(in) :: orig
integer :: n_par, n_prt, n_vtx
integer :: i
n_par = size (orig%par)
n_prt = orig%get_n_field ()
n_vtx = orig%get_n_vtx ()
call model%basic_init (orig%get_name (), n_par, n_prt, n_vtx)
model%md5sum = orig%md5sum
do i = 1, n_par
    call model%copy_parameter (i, orig%par(i))
end do
model%init_external_parameters => orig%init_external_parameters
call model%copy_from (orig)
model%max_par_name_length = orig%max_par_name_length
call model%append_field_vars ()
end subroutine model_copy

```

(Obsolete:) Turn a pointer to a model into a true copy, i.e., a new instance.  
Reset: delete this instance.

```

## 27.5 The SUSY Les Houches Accord

The SUSY Les Houches Accord defines a standard interfaces for storing the physics data of SUSY models. Here, we provide the means for reading, storing, and writing such data.

```
(slha_interface.f90)≡
  ⟨File header⟩

  module slha_interface

    ⟨Use kinds⟩
    ⟨Use strings⟩
    use io_units
    use constants
    use string_utils, only: upper_case
    use unit_tests
    use system_defs, only: VERSION_STRING
    use system_defs, only: EOF
    use diagnostics
    use os_interface
    use ifiles
    use lexers
    use syntax_rules
    use parser
    use variables
    use models

    ⟨Standard module head⟩

    ⟨SLHA: public⟩

    ⟨SLHA: parameters⟩

    ⟨SLHA: variables⟩

    save

    contains

    ⟨SLHA: procedures⟩

    ⟨SLHA: tests⟩

  end module slha_interface
```

### 27.5.1 Preprocessor

SLHA is a mixed-format standard. It should be read in assuming free format (but line-oriented), but it has some fixed-format elements.

To overcome this difficulty, we implement a preprocessing step which transforms the SLHA into a format that can be swallowed by our generic free-format lexer and parser. Each line with a blank first character is assumed to be a

data line. We prepend a 'DATA' keyword to these lines. Furthermore, to enforce line-orientation, each line is appended a '\$' key which is recognized by the parser. To do this properly, we first remove trailing comments, and skip lines consisting only of comments.

The preprocessor reads from a stream and puts out an `ifile`. Blocks that are not recognized are skipped. For some blocks, data items are quoted, so they can be read as strings if necessary.

```

⟨SLHA: parameters⟩≡
    integer, parameter :: MODE_SKIP = 0, MODE_DATA = 1, MODE_INFO = 2

⟨SLHA: procedures⟩≡
    subroutine slha_preprocess (stream, ifile)

    end subroutine define_slha_syntax

```

The SLHA specification allows for string data items in certain places. Currently, we do not interpret them, but the strings, which are not quoted, must be parsed

somehow. The hack for this problem is to allow essentially all characters as special characters, so the string can be read before it is discarded.

```
<SLHA: public>+≡
    public :: lexer_init_slha

<SLHA: procedures>+≡
    subroutine lexer_init_slha (lexer)
        type(lexer_t), intent(out) :: lexer

        if (associated (pn_item)) then
            call var_list%set_real (name, get_real_parameter (pn_item), &
                is_known=.true., ignore=.true.)
        end if
    end subroutine set_matrix_element
```

### Transfer data from variables to SLHA

Get a real/integer parameter with index *i* from the variable list and write it to the current output file. In the integer case, we account for the fact that the variable is type real. If it does not exist, do nothing.

```
(SLHA: procedures)+≡
    subroutine write_integer_data_item (u, code, name, var_list, comment)
        integer, intent(in) :: u
        integer, intent(in) :: code
        type(string_t), intent(in) :: name
        type(var_list_t), intent(in) :: var_list
        character(*), intent(in) :: comment
        integer :: item
        if (var_list%contains (name)) then
            item = nint (var_list%get_rval (name))
            call write_integer_parameter (u, code, item, comment)
        end if
    end subroutine write_integer_data_item

    subroutine write_real_data_item (u, code, name, var_list, comment)
        integer, intent(in) :: u
        integer, intent(in) :: code
        type(string_t), intent(in) :: name
        type(var_list_t), intent(in) :: var_list
        character(*), intent(in) :: comment
        real(default) :: item
        if (var_list%contains (name)) then
            item = var_list%get_rval (name)
            call write_real_parameter (u, code, item, comment)
        end if
    end subroutine write_real_data_item
```

Get a real data item with two integer indices from the variable list and write it to the current output file. If it does not exist, do nothing.

```
(SLHA: procedures)+≡
    subroutine write_matrix_element (u, code1, code2, name, var_list, comment)
        integer, intent(in) :: u
        integer, intent(in) :: code1, code2
        type(string_t), intent(in) :: name
        type(var_list_t), intent(in) :: var_list
        character(*), intent(in) :: comment
        real(default) :: item
        if (var_list%contains (name)) then
            item = var_list%get_rval (name)
            call write_real_matrix_element (u, code1, code2, item, comment)
        end if
    end subroutine write_matrix_element
```

#### 27.5.4 Auxiliary function

Write a block header.

```
(SLHA: procedures)+≡
subroutine write_block_header (u, name, comment)
    integer, intent(in) :: u
    character(*), intent(in) :: name, comment
    write (u, "(A,1x,A,3x,'#',1x,A)") "BLOCK", name, comment
end subroutine write_block_header
```

Extract a real parameter that may be defined real or integer, signed or unsigned.

```
(SLHA: procedures)+≡
function get_real_parameter (pn_item) result (var)
    real(default) :: var
    type(parse_node_t), intent(in), target :: pn_item
    type(parse_node_t), pointer :: pn_sign, pn_var
    integer :: sign
    select case (char (parse_node_get_rule_key (pn_item)))
    case ("signed_number")
        pn_sign => parse_node_get_sub_ptr (pn_item)
        pn_var => parse_node_get_next_ptr (pn_sign)
        select case (char (parse_node_get_key (pn_sign)))
        case ("+"); sign = +1

## SMINPUTS

Read SM parameters and update the variable list accordingly. If a parameter is not defined in the block, we use the previous value from the model variable list. For the basic parameters we have to do a small recalculation, since SLHA uses the  $G_F\text{-}\alpha\text{-}m_Z$  scheme, while WHIZARD derives them from  $G_F$ ,  $m_W$ , and  $m_Z$ .

    call set_data_item (pn_block, 5, var_str ("nmu"), var_list)
end subroutine slha_handle_NMSSMRUN

```

### 27.5.5 Parser

Read a SLHA file from stream, including preprocessing, and make up a parse tree.

```
<SLHA: procedures>+≡
    subroutine slha_parse_stream (stream, parse_tree)
        type(stream_t), intent(inout), target :: stream
        type(parse_tree_t), intent(out) :: parse_tree
        type(ifile_t) :: ifile
        type(lexer_t) :: lexer
        type(stream_t), target :: stream_tmp
        call slha_preprocess (stream, ifile)
        call stream_init (stream_tmp, ifile)
        call lexer_init_slha (lexer)
        call lexer_assign_stream (lexer, stream_tmp)
        call parse_tree_init (parse_tree, syntax_slha, lexer)
        call lexer_final (lexer)
        call stream_final (stream_tmp)
        call ifile_final (ifile)
    end subroutine slha_parse_stream
```

Read a SLHA file chosen by name. Check first the current directory, then the directory where SUSY input files should be located.

Required for test:

```
<SLHA: public>+≡
    public :: slha_parse_file

<SLHA: procedures>+≡
    subroutine slha_parse_file (file, os_data, parse_tree)
        type(string_t), intent(in) :: file
        type(os_data_t), intent(in) :: os_data
        type(parse_tree_t), intent(out) :: parse_tree
        logical :: exist
        type(string_t) :: filename
        type(stream_t), target :: stream
        call msg_message ("Reading SLHA input file '" // char (file) // "'")
        filename = file
        inquire (file=char(filename), exist=exist)
        if (.not. exist) then
            filename = os_data%whizard_susypath // "/" // file
            inquire (file=char(filename), exist=exist)
            if (.not. exist) then
                call msg_fatal ("SLHA input file '" // char (file) // "' not found")
                return
            end if
        end if
        call stream_init (stream, char (filename))
        call slha_parse_stream (stream, parse_tree)
        call stream_final (stream)
    end subroutine slha_parse_file
```

## 27.5.6 API

Read the SLHA file, parse it, and interpret the parse tree. The model parameters retrieved from the file will be inserted into the appropriate model, which is loaded and modified in the background. The pointer to this model is returned as the last argument.

```
<SLHA: public>+≡
    public :: slha_read_file

<SLHA: procedures>+≡
    subroutine slha_read_file &
        (file, os_data, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(os_data_t), intent(in) :: os_data
        type(model_t), intent(inout), target :: model
        logical, intent(in) :: input, spectrum, decays
        type(parse_tree_t) :: parse_tree
        call slha_parse_file (file, os_data, parse_tree)
        if (associated (parse_tree%get_root_ptr ())) then
            call slha_interpret_parse_tree &
                (parse_tree, model, input, spectrum, decays)
            call parse_tree_final (parse_tree)
            call model%update_parameters ()
        end if
    end subroutine slha_read_file
```

Write the SLHA contents, as far as possible, to external file.

```
<SLHA: public>+≡
    public :: slha_write_file

<SLHA: procedures>+≡
    subroutine slha_write_file (file, model, input, spectrum, decays)
        type(string_t), intent(in) :: file
        type(model_t), target, intent(in) :: model
        logical, intent(in) :: input, spectrum, decays
        integer :: mssm_type
        integer :: u
        u = free_unit ()
        call msg_message ("Writing SLHA output file '" // char (file) // "'")
        open (unit=u, file=char(file), action="write", status="replace")
        write (u, "(A)") "# SUSY Les Houches Accord"
        write (u, "(A)") "# Output generated by " // trim (VERSION_STRING)
        call slha_write_MODSEL (u, model, mssm_type)
        if (input) then
            call slha_write_SMINPUTS (u, model)
            call slha_write_MINPAR (u, model, mssm_type)
        end if
        if (spectrum) then
            call msg_bug ("SLHA: spectrum output not supported yet")
        end if
        if (decays) then
            call msg_bug ("SLHA: decays output not supported yet")
        end if
        close (u)
```

```
    end subroutine slha_write_file
```

### 27.5.7 Unit tests

## Chapter 28

# Integration and Process Objects

This is the central part of the WHIZARD package. It provides the functionality for evaluating structure functions, kinematics and matrix elements, integration and event generation. It combines the various parts that deal with those tasks individually and organizes the data transfer between them.

**subevt\_expr** This enables process observables as (abstract) expressions, to be evaluated for each process call.

**parton\_states** A `parton_state_t` object represents an elementary partonic interaction. There are two versions: one for the isolated elementary process, one for the elementary process convoluted with the structure-function chain. The parton state is an effective state. It needs not coincide with the seed-kinematics state which is used in evaluating phase space.

**processes** Here, all pieces are combined for the purpose of evaluating the elementary processes. The whole algorithm is coded in terms of abstract data types as defined in the appropriate modules: `prc_core` for matrix-element evaluation, `prc_core_def` for the associated configuration and driver, `sf_base` for beams and structure-functions, `phs_base` for phase space, and `mci_base` for integration and event generation.

**process\_stacks** Process stacks collect process objects.

### 28.1 Process observables

We define an abstract `subevt_expr_t` object as an extension of the `subevt_t` type. The object contains a local variable list, variable instances (as targets for pointers in the variable list), and evaluation trees. The evaluation trees reference both the variables and the `subevt`.

There are two instances of the abstract type: one for process instances, one for physical events. Both have a common logical expression `selection` which determines whether the object passes user-defined cuts.

The intention is that we fill the `subevt_t` base object and compute the variables once we have evaluated a kinematical phase space point (or a complete

event). We then evaluate the expressions and can use the results in further calculations.

The `process_expr_t` extension contains furthermore scale and weight expressions. The `event_expr_t` extension contains a reweighting-factor expression and a logical expression for event analysis. In practice, we will link the variable list of the `event_obs` object to the variable list of the currently active `process_obs` object, such that the process variables are available to both objects. Event variables are meaningful only for physical events.

Note that there are unit tests, but they are deferred to the `expr_tests` module.

```
(subevt_expr.f90)≡
  ⟨File header⟩
  module subevt_expr

    ⟨Use kinds⟩
    ⟨Use strings⟩
    use io_units
    use format_utils, only: write_separator
    use diagnostics
    use lorentz
    use subevents
    use variables
    use flavors
    use quantum_numbers
    use interactions
    use particles
    use expr_base

    ⟨Standard module head⟩

    ⟨Subevt expr: public⟩

    ⟨Subevt expr: types⟩

    ⟨Subevt expr: interfaces⟩

    contains

    ⟨Subevt expr: procedures⟩

  end module subevt_expr
```

### 28.1.1 Abstract base type

```
⟨Subevt expr: types)≡
  type, extends (subevt_t), abstract :: subevt_expr_t
    logical :: subevt_filled = .false.
    type(var_list_t) :: var_list
    real(default) :: sqrts_hat = 0
    integer :: n_in = 0
    integer :: n_out = 0
    integer :: n_tot = 0
    logical :: has_selection = .false.
```

```

    class(expr_t), allocatable :: selection
contains
  <Subevt expr: subevt expr: TBP>
end type subevt_expr_t

```

Output: Base and extended version. We already have a `write` routine for the `subevt_t` parent type.

```

<Subevt expr: subevt expr: TBP>≡
  procedure :: base_write => subevt_expr_write
  <Subevt expr: procedures>≡
    subroutine subevt_expr_write (object, unit, pacified)
      class(subevt_expr_t), intent(in) :: object
      integer, intent(in), optional :: unit
      logical, intent(in), optional :: pacified
      integer :: u
      u = given_output_unit (unit)
      write (u, "(1x,A)") "Local variables:"
      call write_separator (u)
      call var_list_write (object%var_list, u, follow_link=.false., &
        pacified = pacified)
      call write_separator (u)
      if (object%subevt_filled) then
        call object%subevt_t%write (u, pacified = pacified)
        if (object%has_selection) then
          call write_separator (u)
          write (u, "(1x,A)") "Selection expression:"
          call write_separator (u)
          call object%selection%write (u)
        end if
      else
        write (u, "(1x,A)") "subevt: [undefined]"
      end if
    end subroutine subevt_expr_write

```

Finalizer.

```

<Subevt expr: subevt expr: TBP>+≡
  procedure (subevt_expr_final), deferred :: final
  procedure :: base_final => subevt_expr_final
  <Subevt expr: procedures>+≡
    subroutine subevt_expr_final (object)
      class(subevt_expr_t), intent(inout) :: object
      call object%var_list%final ()
      if (object%has_selection) then
        call object%selection%final ()
      end if
    end subroutine subevt_expr_final

```

### 28.1.2 Initialization

Initialization: define local variables and establish pointers.

The common variables are `sqrt`s (the nominal beam energy, fixed), `sqrt_hat` (the actual energy), `n_in`, `n_out`, and `n_tot` for the `subevt`. With the exception of `sqrt`s, all are implemented as pointers to subobjects.

```
(Subevt expr: subevt expr: TBP) +≡
procedure (subevt_expr_setup_vars), deferred :: setup_vars
procedure :: base_setup_vars => subevt_expr_setup_vars
(Subevt expr: procedures) +≡
subroutine subevt_expr_setup_vars (expr, sqrt)
  class(subevt_expr_t), intent(inout), target :: expr
  real(default), intent(in) :: sqrt
  call expr%var_list%final ()
  call var_list_append_real (expr%var_list, &
    var_str ("sqrt"), sqrt, &
    locked = .true., verbose = .false., intrinsic = .true.)
  call var_list_append_real_ptr (expr%var_list, &
    var_str ("sqrt_hat"), expr%sqrt_hat, &
    is_known = expr%subevt_filled, &
    locked = .true., verbose = .false., intrinsic = .true.)
  call var_list_append_int_ptr (expr%var_list, &
    var_str ("n_in"), expr%n_in, &
    is_known = expr%subevt_filled, &
    locked = .true., verbose = .false., intrinsic = .true.)
  call var_list_append_int_ptr (expr%var_list, &
    var_str ("n_out"), expr%n_out, &
    is_known = expr%subevt_filled, &
    locked = .true., verbose = .false., intrinsic = .true.)
  call var_list_append_int_ptr (expr%var_list, &
    var_str ("n_tot"), expr%n_tot, &
    is_known = expr%subevt_filled, &
    locked = .true., verbose = .false., intrinsic = .true.)
end subroutine subevt_expr_setup_vars
```

Append the subevent expr (its base-type core) itself to the variable list, if it is not yet present.

```
(Subevt expr: subevt expr: TBP) +≡
procedure :: setup_var_self => subevt_expr_setup_var_self
(Subevt expr: procedures) +≡
subroutine subevt_expr_setup_var_self (expr)
  class(subevt_expr_t), intent(inout), target :: expr
  if (.not. expr%var_list%contains (var_str ("@evt"))) then
    call var_list_append_subevt_ptr &
      (expr%var_list, &
       var_str ("@evt"), expr%subevt_t, &
       is_known = expr%subevt_filled, &
       locked = .true., verbose = .false., intrinsic=.true.)
  end if
end subroutine subevt_expr_setup_var_self
```

Link a variable list to the local one. This could be done event by event, but before evaluating expressions.

```
(Subevt expr: subevt expr: TBP) +≡
procedure :: link_var_list => subevt_expr_link_var_list
```

```

⟨Subevt expr: procedures⟩+≡
    subroutine subevt_expr_link_var_list (expr, var_list)
        class(subevt_expr_t), intent(inout) :: expr
        type(var_list_t), intent(in), target :: var_list
        call expr%var_list%link (var_list)
    end subroutine subevt_expr_link_var_list

```

Compile the selection expression. If there is no expression, the build method won't allocate the expression object.

```

⟨Subevt expr: subevt expr: TBP⟩+≡
    procedure :: setup_selection => subevt_expr_setup_selection

⟨Subevt expr: procedures⟩+≡
    subroutine subevt_expr_setup_selection (expr, ef_cuts)
        class(subevt_expr_t), intent(inout), target :: expr
        class(expr_factory_t), intent(in) :: ef_cuts
        call ef_cuts%build (expr%selection)
        if (allocated (expr%selection)) then
            call expr%setup_var_self ()
            call expr%selection%setup_lexpr (expr%var_list)
            expr%has_selection = .true.
        end if
    end subroutine subevt_expr_setup_selection

```

### 28.1.3 Evaluation

Reset to initial state, i.e., mark the subevt as invalid.

```

⟨Subevt expr: subevt expr: TBP⟩+≡
    procedure :: reset => subevt_expr_reset
    procedure :: base_reset => subevt_expr_reset

⟨Subevt expr: procedures⟩+≡
    subroutine subevt_expr_reset (expr)
        class(subevt_expr_t), intent(inout) :: expr
        expr%subevt_filled = .false.
    end subroutine subevt_expr_reset

```

Evaluate the selection expression and return the result. There is also a deferred version: this should evaluate the remaining expressions if the event has passed.

```

⟨Subevt expr: subevt expr: TBP⟩+≡
    procedure :: base_evaluate => subevt_expr_evaluate

⟨Subevt expr: procedures⟩+≡
    subroutine subevt_expr_evaluate (expr, passed)
        class(subevt_expr_t), intent(inout) :: expr
        logical, intent(out) :: passed
        if (expr%has_selection) then
            call expr%selection%evaluate ()
            if (expr%selection%is_known ()) then
                passed = expr%selection%get_log ()
            else
                call msg_error ("Evaluate selection expression: result undefined")
            end if
        end if
    end subroutine subevt_expr_evaluate

```

```

        passed = .false.
    end if
else
    passed = .true.
end if
end subroutine subevt_expr_evaluate

```

#### 28.1.4 Implementation for partonic events

This implementation contains the expressions that we can evaluate for the partonic process during integration.

```

<Subevt expr: public>≡
    public :: parton_expr_t

<Subevt expr: types>+≡
    type, extends (subevt_expr_t) :: parton_expr_t
        integer, dimension(:), allocatable :: i_beam
        integer, dimension(:), allocatable :: i_in
        integer, dimension(:), allocatable :: i_out
        logical :: has_scale = .false.
        logical :: has_fac_scale = .false.
        logical :: has_ren_scale = .false.
        logical :: has_weight = .false.
        class(expr_t), allocatable :: scale
        class(expr_t), allocatable :: fac_scale
        class(expr_t), allocatable :: ren_scale
        class(expr_t), allocatable :: weight
    contains
        <Subevt expr: parton expr: TBP>
    end type parton_expr_t

```

Finalizer.

```

<Subevt expr: parton expr: TBP>≡
    procedure :: final => parton_expr_final

<Subevt expr: procedures>+≡
    subroutine parton_expr_final (object)
        class(parton_expr_t), intent(inout) :: object
        call object%base_final ()
        if (object%has_scale) then
            call object%scale%final ()

Filling the partonic state consists of two parts. The first routine prepares the subevt without assigning momenta. It takes the particles from an `interaction_t`. It needs the indices and flavors for the beam, incoming, and outgoing particles.

We can assume that the particle content of the subevt does not change. Therefore, we set the event variables `n_in`, `n_out`, `n_tot` already in this initialization step.

```

### 28.1.5 Implementation for full events

This implementation contains the expressions that we can evaluate for the full event. It also contains data that pertain to the event, suitable for communication with external event formats. These data simultaneously serve as pointer targets for the variable lists hidden in the expressions (eval trees).

Squared matrix element and weight values: when reading events from file, the `ref` value is the number in the file, while the `prc` value is the number that we calculate from the momenta in the file, possibly with different parameters. When generating events the first time, or if we do not recalculate, the numbers should coincide. Furthermore, the array of `alt` values is copied from an array of alternative event records. These values should represent calculated values.

```

end if
end subroutine event_expr_evaluate

```

## 28.2 Parton states

A `parton_state_t` object contains the effective kinematics and dynamics of an elementary partonic interaction, with or without the beam/structure function state included. The type is abstract and has two distinct extensions. The `isolated_state_t` extension describes the isolated elementary interaction where the `int_eff` subobject contains the complex transition amplitude, exclusive in all quantum numbers. The particle content and kinematics describe the effective partonic state. The `connected_state_t` extension contains the partonic `subevt` and the expressions for cuts and scales which use it.

In the isolated state, the effective partonic interaction may either be identical to the hard interaction, in which case it is just a pointer to the latter. Or it may involve a rearrangement of partons, in which case we allocate it explicitly and flag this by `int_is_allocated`.

The `trace` evaluator contains the absolute square of the effective transition amplitude matrix, summed over final states. It is also summed over initial states, depending on the the beam setup allows. The result is used for integration.

The `matrix` evaluator is the counterpart of `trace` which is kept exclusive in all observable quantum numbers. The `flows` evaluator is furthermore exclusive in colors, but neglecting all color interference. The `matrix` and `flows` evaluators are filled only for sampling points that become part of physical events.

Note: It would be natural to make the evaluators allocatable. However, this causes memory corruption in gfortran 4.6.3. The extra `has_XXX` flags indicate whether evaluators are active, instead.

This module contains no unit tests. The tests are covered by the `processes` module below.

```

### 28.2.1 Abstract base type

The common part are the evaluators, one for the trace (summed over all quantum numbers), one for the transition matrix (summed only over unobservable quantum numbers), and one for the flow distribution (transition matrix without interferences, exclusive in color flow).

```

⟨Parton states: types⟩≡
  type, abstract :: parton_state_t
    logical :: has_trace = .false.
    logical :: has_matrix = .false.
    logical :: has_flows = .false.
    type(evaluator_t) :: trace
    type(evaluator_t) :: matrix
    type(evaluator_t) :: flows
  contains
  ⟨Parton states: parton state: TBP⟩
end type parton_state_t

```

The `isolated_state_t` extension contains the `sf_chain_eff` object and the (hard) effective interaction `int_eff`, separately, both implemented as a pointer. The evaluators (trace, matrix, flows) apply to the hard interaction only.

If the effective interaction differs from the hard interaction, the pointer is allocated explicitly. Analogously for `sf_chain_eff`.

```
(Parton states: public)≡
    public :: isolated_state_t

(Parton states: types)+≡
    type, extends (parton_state_t) :: isolated_state_t
        logical :: sf_chain_is_allocated = .false.
        type(sf_chain_instance_t), pointer :: sf_chain_eff => null ()
        logical :: int_is_allocated = .false.
        type(interaction_t), pointer :: int_eff => null ()
    contains
        (Parton states: isolated state: TBP)
    end type isolated_state_t
```

The `connected_state_t` extension contains all data that enable the evaluation of observables for the effective connected state. The evaluators connect the (effective) structure-function chain and hard interaction that were kept separate in the `isolated_state_t`.

The `flows_sf` evaluator is an extended copy of the structure-function

The `expr` subobject consists of the `subevt`, a simple event record, expressions for cuts etc. which refer to this record, and a `var_list` which contains event-specific variables, linked to the process variable list. Variables used within the expressions are looked up in `var_list`.

```
(Parton states: types)+≡
    public :: connected_state_t

(Parton states: types)+≡
    type, extends (parton_state_t) :: connected_state_t
        type(state_flv_content_t) :: state_flv
        logical :: has_flows_sf = .false.
        type(evaluator_t) :: flows_sf
        logical :: has_expr = .false.
        type(parton_expr_t) :: expr
    contains
        (Parton states: connected state: TBP)
    end type connected_state_t
```

Output: each evaluator is written only when it is active. The `sf_chain` is only written if it is explicitly allocated.

```
(Parton states: parton state: TBP)≡
    procedure :: write => parton_state_write

(Parton states: procedures)≡

        deallocate (state%int_eff)
        state%int_is_allocated = .false.
      end if
      if (state%sf_chain_is_allocated) then
        call state%sf_chain_eff%final ()
      end if
    end select
  end subroutine parton_state_final

```

### 28.2.2 Common Initialization

Initialize the isolated parton state. In this version, the effective structure-function chain `sf_chain_eff` and the effective interaction `int_eff` both are trivial pointers to the seed structure-function chain and to the hard interaction, respectively.

```

⟨Parton states: isolated state: TBP⟩≡
  procedure :: init => isolated_state_init_pointers

⟨Parton states: procedures⟩+≡
  subroutine isolated_state_init_pointers (state, sf_chain, int)
    class(isolated_state_t), intent(out) :: state
    type(sf_chain_instance_t), intent(in), target :: sf_chain
    type(interaction_t), intent(in), target :: int
    state%sf_chain_eff => sf_chain
    state%int_eff => int
  end subroutine isolated_state_init_pointers

```

### 28.2.3 Evaluator initialization: isolated state

Create an evaluator for the trace of the squared transition matrix. The trace goes over all outgoing quantum numbers. Whether we trace over incoming quantum numbers other than color, depends on the given `qn_mask_in`.

There are two options: explicitly computing the color factor table (`use_cf` false; `nc` defined), or taking the color factor table from the hard matrix element data.

```
(Parton states: isolated state: TBP)+≡
procedure :: setup_square_trace => isolated_state_setup_square_trace
(Parton states: procedures)+≡
subroutine isolated_state_setup_square_trace (state, core, qn_mask_in, &
                                               col)
  class(isolated_state_t), intent(inout), target :: state
  class(prc_core_t), intent(in) :: core
  type(quantum_numbers_mask_t), dimension(:), intent(in) :: qn_mask_in
  integer, dimension(:), intent(in) :: col
  type(quantum_numbers_mask_t), dimension(:), allocatable :: qn_mask
  associate (data => core%data)
    allocate (qn_mask (data%n_in + data%n_out))
    qn_mask(:data%n_in) = &
      quantum_numbers_mask (.false., .true., .false.) &
      .or. qn_mask_in
    qn_mask(data%n_in+1:) = &
      quantum_numbers_mask (.true., .true., .true.)
  if (core%use_color_factors) then
    call state%trace%init_square (state%int_eff, qn_mask, &
      col_flow_index = data%cf_index, &
      col_factor = data%color_factors, &
      col_index_hi = col, &
      nc = core%nc)
  else
    call state%trace%init_square (state%int_eff, qn_mask, nc = core%nc)
  end if
  end associate
  state%has_trace = .true.
end subroutine isolated_state_setup_square_trace
```

Setup the evaluator for the transition matrix, exclusive in helicities where this is requested.

For all unstable final-state particles we keep polarization according to the applicable decay options. If the process is a decay itself, this applies also to the initial state.

For all polarized final-state particles, we keep polarization including off-diagonal entries. We drop helicity completely for unpolarized final-state particles.

For the initial state, if the particle has not been handled yet, we apply the provided `qn_mask_in` which communicates the beam properties.

```
(Parton states: isolated state: TBP)+≡
procedure :: setup_square_matrix => isolated_state_setup_square_matrix
```

```

⟨Parton states: procedures⟩+≡
    subroutine isolated_state_setup_square_matrix &
        (state, core, model, qn_mask_in, col)
        class(isolated_state_t), intent(inout), target :: state
        class(prc_core_t), intent(in) :: core
        class(model_data_t), intent(in), target :: model
        type(quantum_numbers_mask_t), dimension(:, ), intent(in) :: qn_mask_in
        integer, dimension(:, ), intent(in) :: col
        type(quantum_numbers_mask_t), dimension(:, ), allocatable :: qn_mask
        type(flavor_t), dimension(:, ), allocatable :: flv
        integer :: i
        logical :: helmask, helmask_hd
        associate (data => core%data)
            allocate (qn_mask (data%n_in + data%n_out))
            allocate (flv (data%n_flv))
            do i = 1, data%n_in + data%n_out
                call flv%init (data%flv_state(i,:), model)
                if ((data%n_in == 1 .or. i > data%n_in) &
                    .and. any (.not. flv%is_stable ()))
                    helmask = all (flv%decays_isotropically ())
                    helmask_hd = all (flv%decays_diagonal ())
                    qn_mask(i) = quantum_numbers_mask (.false., .true., helmask, &
                        mask_hd = helmask_hd)
                else if (i > data%n_in) then
                    helmask = all (.not. flv%is_polarized ())
                    qn_mask(i) = quantum_numbers_mask (.false., .true., helmask)
                else
                    qn_mask(i) = quantum_numbers_mask (.false., .true., .false.) &
                        .or. qn_mask_in(i)
                end if
            end do
            if (core%use_color_factors) then
                call state%matrix%init_square (state%int_eff, qn_mask, &
                    col_flow_index = data%cf_index, &
                    col_factor = data%color_factors, &
                    col_index_hi = col, &
                    nc = core%nc)
            else
                call state%matrix%init_square (state%int_eff, &
                    qn_mask, &
                    nc = core%nc)
            end if
        end associate
        state%has_matrix = .true.
    end subroutine isolated_state_setup_square_matrix

```

This procedure initializes the evaluator that computes the contributions to color flows, neglecting color interference. The incoming-particle mask can be used to sum over incoming flavor.

Helicity handling: see above.

```

#### 28.2.4 Evaluator initialization: connected state

Setup a trace evaluator as a product of two evaluators (incoming state, effective interaction). In the result, all quantum numbers are summed over.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`.

The `resonant` flag applies if we want to construct a decay chain. The resonance property can propagate to the final event output.

*(Parton states: connected state: TBP)*≡  
 procedure :: setup\_connected\_trace => connected\_state\_setup\_connected\_trace  
*(Parton states: procedures)*+≡  
 subroutine connected\_state\_setup\_connected\_trace &  
 (state, isolated, int, resonant)  
 class(connected\_state\_t), intent(inout), target :: state  
 type(isolated\_state\_t), intent(in), target :: isolated  
 type(interaction\_t), intent(in), optional, target :: int  
 logical, intent(in), optional :: resonant

```

type(quantum_numbers_mask_t) :: mask
type(interaction_t), pointer :: src_int
mask = quantum_numbers_mask (.true., .true., .true.)
if (present (int)) then
    src_int => int
else
    src_int => isolated%sf_chain_eff%get_out_int_ptr ()
end if
call state%trace%init_product (src_int, isolated%trace, &
    qn_mask_conn = mask, &
    qn_mask_rest = mask, &
    connections_are_resonant = resonant)
state%has_trace = .true.
end subroutine connected_state_setup_connected_trace

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interation). In the intermediate state, color and helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

```

<Parton states: connected state: TBP>+≡
procedure :: setup_connected_matrix => connected_state_setup_connected_matrix
<Parton states: procedures>+≡
subroutine connected_state_setup_connected_matrix &
    (state, isolated, int, resonant, qn_filter_conn)
class(connected_state_t), intent(inout), target :: state
type(isolated_state_t), intent(in), target :: isolated
type(interaction_t), intent(in), optional, target :: int
logical, intent(in), optional :: resonant
type(quantum_numbers_t), intent(in), optional :: qn_filter_conn
type(quantum_numbers_mask_t) :: mask
type(interaction_t), pointer :: src_int
mask = quantum_numbers_mask (.false., .true., .true.)
if (present (int)) then
    src_int => int
else
    src_int => isolated%sf_chain_eff%get_out_int_ptr ()
end if
call state%matrix%init_product &
    (src_int, isolated%matrix, mask, &
    qn_filter_conn = qn_filter_conn, &
    connections_are_resonant = resonant)
state%has_matrix = .true.
end subroutine connected_state_setup_connected_matrix

```

Setup a matrix evaluator as a product of two evaluators (incoming state, effective interation). In the intermediate state, only helicity is summed over. In the final state, we keep the quantum numbers which are present in the original evaluators.

If the optional `int` interaction is provided, use this for the first factor in the convolution. Otherwise, use the final interaction of the stored `sf_chain`, after creating an intermediate interaction that includes a correlated color state. We assume that for a caller-provided `int`, this is not necessary.

<Parton states: connected state: TBP>+≡

```

procedure :: setup_connected_flows => connected_state_setup_connected_flows
⟨Parton states: procedures⟩+≡
    subroutine connected_state_setup_connected_flows &

        state_flv = state%state_flv
    end function connected_state_get_state_flv

```

## 28.2.5 Cuts and expressions

Set up the `subevt` that corresponds to the connected interaction. The index arrays refer to the interaction.

We assign the particles as follows: the beam particles are the first two (decay process: one) entries in the trace evaluator. The incoming partons are identified by their link to the outgoing partons of the structure-function chain. The outgoing partons are those of the trace evaluator, which include radiated partons during the structure-function chain.

```
(Parton states: connected state: TBP)+≡
procedure :: setup_subevt => connected_state_setup_subevt
(Parton states: procedures)+≡
subroutine connected_state_setup_subevt (state, sf_chain, f_beam, f_in, f_out)
  class(connected_state_t), intent(inout), target :: state
  type(sf_chain_instance_t), intent(in), target :: sf_chain
  type(flavor_t), dimension(:), intent(in) :: f_beam, f_in, f_out
  integer :: n_beam, n_in, n_out, n_vir, n_tot, i, j
  integer, dimension(:), allocatable :: i_beam, i_in, i_out
  integer :: sf_out_i
  type(interaction_t), pointer :: sf_int
  sf_int => sf_chain%get_out_int_ptr ()
  n_beam = size (f_beam)
  n_in = size (f_in)
  n_out = size (f_out)
  n_vir = state%trace%get_n_vir ()
  n_tot = state%trace%get_n_tot ()
  allocate (i_beam (n_beam), i_in (n_in), i_out (n_out))
  i_beam = [(i, i = 1, n_beam)]
  do j = 1, n_in
    sf_out_i = sf_chain%get_out_i (j)
    i_in(j) = interaction_find_link &
      (state%trace%interaction_t, sf_int, sf_out_i)
  end do
  i_out = [(i, i = n_vir + 1, n_tot)]
  call state%expr%setup_subevt (state%trace%interaction_t, &
    i_beam, i_in, i_out, f_beam, f_in, f_out)
  state%has_expr = .true.
end subroutine connected_state_setup_subevt
```

Initialize the variable list specific for this state/term. We insert event variables (`sqrts_hat`) and link the process variable list. The variable list acquires pointers to subobjects of `state`, which must therefore have a `target` attribute.

```
(Parton states: connected state: TBP)+≡
procedure :: setup_var_list => connected_state_setup_var_list
(Parton states: procedures)+≡
subroutine connected_state_setup_var_list (state, process_var_list, beam_data)
  class(connected_state_t), intent(inout), target :: state
  type(var_list_t), intent(in), target :: process_var_list
  type(bean_data_t), intent(in) :: beam_data
  call state%expr%setup_vars (beam_data_get_sqrts (beam_data))
  call state%expr%link_var_list (process_var_list)
end subroutine connected_state_setup_var_list
```

Allocate the cut expression etc.

```
(Parton states: connected state: TBP)+≡
procedure :: setup_cuts => connected_state_setup_cuts
procedure :: setup_scale => connected_state_setup_scale
procedure :: setup_fac_scale => connected_state_setup_fac_scale
procedure :: setup_ren_scale => connected_state_setup_ren_scale
procedure :: setup_weight => connected_state_setup_weight

(Parton states: procedures)+≡
subroutine connected_state_setup_cuts (state, ef_cuts)
  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_cuts
  call state%expr%setup_selection (ef_cuts)
end subroutine connected_state_setup_cuts

subroutine connected_state_setup_scale (state, ef_scale)
  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_scale
  call state%expr%setup_scale (ef_scale)
end subroutine connected_state_setup_scale

subroutine connected_state_setup_fac_scale (state, ef_fac_scale)
  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_fac_scale
  call state%expr%setup_fac_scale (ef_fac_scale)
end subroutine connected_state_setup_fac_scale

subroutine connected_state_setup_ren_scale (state, ef_ren_scale)
  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_ren_scale
  call state%expr%setup_ren_scale (ef_ren_scale)
end subroutine connected_state_setup_ren_scale

subroutine connected_state_setup_weight (state, ef_weight)
  class(connected_state_t), intent(inout), target :: state
  class(expr_factory_t), intent(in) :: ef_weight
  call state%expr%setup_weight (ef_weight)
end subroutine connected_state_setup_weight
```

Reset the expression object: invalidate the subevt.

```
(Parton states: connected state: TBP)+≡
procedure :: reset_expressions => connected_state_reset_expressions

(Parton states: procedures)+≡
subroutine connected_state_reset_expressions (state)
  class(connected_state_t), intent(inout) :: state
  if (state%has_expr) call state%expr%reset ()
end subroutine connected_state_reset_expressions
```

## 28.2.6 Evaluation

Transfer momenta to the trace evaluator and fill the `subevt` with this effective kinematics, if applicable.

Note: we may want to apply a boost for the `subevt`.

```
(Parton states: parton state: TBP) +≡
    procedure :: receive_kinematics => parton_state_receive_kinematics
(Parton states: procedures) +≡
    subroutine parton_state_receive_kinematics (state)
        class(parton_state_t), intent(inout), target :: state
        if (state%has_trace) then
            call state%trace%receive_momenta ()
            select type (state)
            class is (connected_state_t)
                if (state%has_expr) then
                    call state%expr%fill_subevt (state%trace%interaction_t)
                end if
            end select
        end if
    end subroutine parton_state_receive_kinematics
```

Recover kinematics: We assume that the trace evaluator is filled with momenta. Send those momenta back to the sources, then fill the variables and subevent as above.

The incoming momenta of the connected state are not connected to the isolated state but to the beam interaction. Therefore, the incoming momenta within the isolated state do not become defined, yet. Instead, we reconstruct the beam (and ISR) momentum configuration.

```
(Parton states: parton state: TBP) +≡
    procedure :: send_kinematics => parton_state_send_kinematics
(Parton states: procedures) +≡
    subroutine parton_state_send_kinematics (state)
        class(parton_state_t), intent(inout), target :: state
        if (state%has_trace) then
            call interaction_send_momenta (state%trace%interaction_t)
            select type (state)
            class is (connected_state_t)
                call state%expr%fill_subevt (state%trace%interaction_t)
            end select
        end if
    end subroutine parton_state_send_kinematics
```

Evaluate the expressions. The routine evaluates first the cut expression. If the event passes, it evaluates the other expressions. Where no expressions are defined, default values are inserted.

```
(Parton states: connected state: TBP) +≡
    procedure :: evaluate_expressions => connected_state_evaluate_expressions
(Parton states: procedures) +≡
    subroutine connected_state_evaluate_expressions (state, passed, &
        scale, fac_scale, ren_scale, weight, scale_forced)
```

```

    class(connected_state_t), intent(inout) :: state
    logical, intent(out) :: passed
    real(default), intent(out) :: scale, fac_scale, ren_scale, weight
    real(default), intent(in), allocatable, optional :: scale_forced
    if (state%has_expr) then
        call state%expr%evaluate (passed, scale, fac_scale, ren_scale, weight, &
            scale_forced)
    end if
end subroutine connected_state_evaluate_expressions

```

Evaluate the structure-function chain, if it is allocated explicitly. The argument is the factorization scale.

If the chain is merely a pointer, the chain should already be evaluated at this point.

```

⟨Parton states: isolated state: TBP⟩+≡
    procedure :: evaluate_sf_chain => isolated_state_evaluate_sf_chain
⟨Parton states: procedures⟩+≡
    subroutine isolated_state_evaluate_sf_chain (state, fac_scale)
        class(isolated_state_t), intent(inout) :: state
        real(default), intent(in) :: fac_scale
        if (state%sf_chain_is_allocated) then
            call state%sf_chain_eff%evaluate (fac_scale)
        end if
    end subroutine isolated_state_evaluate_sf_chain

```

Evaluate the trace.

```

⟨Parton states: parton state: TBP⟩+≡
    procedure :: evaluate_trace => parton_state_evaluate_trace
⟨Parton states: procedures⟩+≡
    subroutine parton_state_evaluate_trace (state)
        class(parton_state_t), intent(inout) :: state
        if (state%has_trace) then
            call state%trace%evaluate ()
        end if
    end subroutine parton_state_evaluate_trace

```

Evaluate the extra evaluators that we need for physical events.

```

⟨Parton states: parton state: TBP⟩+≡
    procedure :: evaluate_event_data => parton_state_evaluate_event_data
⟨Parton states: procedures⟩+≡
    subroutine parton_state_evaluate_event_data (state)
        class(parton_state_t), intent(inout) :: state
        select type (state)
        type is (connected_state_t)
        if (state%has_flows_sf) then
            call state%flows_sf%receive_momenta ()
            call state%flows_sf%evaluate ()
        end if
    end select
    if (state%has_matrix) then

```

```

    call state%matrix%receive_momenta ()
    call state%matrix%evaluate ()
end if
if (state%has_flows) then
    call state%flows%receive_momenta ()
    call state%flows%evaluate ()
end if
end subroutine parton_state_evaluate_event_data

```

Normalize the helicity density matrix by its trace, i.e., factor out the trace and put it into an overall normalization factor. The trace and flow evaluators are unchanged.

```

⟨Parton states: parton state: TBP⟩+≡
procedure :: normalize_matrix_by_trace => &
parton_state_normalize_matrix_by_trace

⟨Parton states: procedures⟩+≡
subroutine parton_state_normalize_matrix_by_trace (state)
class(parton_state_t), intent(inout) :: state
if (state%has_matrix) then
    call state%matrix%normalize_by_trace ()
end if
end subroutine parton_state_normalize_matrix_by_trace

```

### 28.2.7 Accessing the state

Three functions return a pointer to the event-relevant interactions.

```

⟨Parton states: parton state: TBP⟩+≡
procedure :: get_trace_int_ptr => parton_state_get_trace_int_ptr
procedure :: get_matrix_int_ptr => parton_state_get_matrix_int_ptr
procedure :: get_flows_int_ptr => parton_state_get_flows_int_ptr

⟨Parton states: procedures⟩+≡
function parton_state_get_trace_int_ptr (state) result (ptr)
class(parton_state_t), intent(in), target :: state
type(interaction_t), pointer :: ptr
if (state%has_trace) then
    ptr => state%trace%interaction_t
else
    ptr => null ()
end if
end function parton_state_get_trace_int_ptr

function parton_state_get_matrix_int_ptr (state) result (ptr)
class(parton_state_t), intent(in), target :: state
type(interaction_t), pointer :: ptr
if (state%has_matrix) then
    ptr => state%matrix%interaction_t
else
    ptr => null ()
end if
end function parton_state_get_matrix_int_ptr

```

```

function parton_state_get_flows_int_ptr (state) result (ptr)
    class(parton_state_t), intent(in), target :: state
    type(interaction_t), pointer :: ptr
    if (state%has_flows) then
        ptr => state%flows%interaction_t
    else
        ptr => null ()
    end if
end function parton_state_get_flows_int_ptr

```

Return the indices of the beam particles and the outgoing particles within the trace (and thus, matrix and flows) evaluator, respectively.

```

⟨Parton states: connected state: TBP⟩+≡
procedure :: get_beam_index => connected_state_get_beam_index
procedure :: get_in_index => connected_state_get_in_index

⟨Parton states: procedures⟩+≡
subroutine connected_state_get_beam_index (state, i_beam)
    class(connected_state_t), intent(in) :: state
    integer, dimension(:), intent(out) :: i_beam
    call state%expr%get_beam_index (i_beam)
end subroutine connected_state_get_beam_index

subroutine connected_state_get_in_index (state, i_in)
    class(connected_state_t), intent(in) :: state
    integer, dimension(:), intent(out) :: i_in
    call state%expr%get_in_index (i_in)
end subroutine connected_state_get_in_index

```

Return the number of outgoing (hard) particles for the state.

```

⟨Parton states: parton state: TBP⟩+≡
procedure :: get_n_out => parton_state_get_n_out

⟨Parton states: procedures⟩+≡
function parton_state_get_n_out (state) result (n)
    class(parton_state_t), intent(in), target :: state
    integer :: n
    n = state%trace%get_n_out ()
end function parton_state_get_n_out

```

## 28.3 Complete Elementary Processes

This module combines hard interactions, phase space, and (for scatterings) structure functions and interfaces them to the integration module.

The process object implements the combination of a fixed beam and structure-function setup with a number of elementary processes. The latter are called process components. The process object represents an entity which is supposedly observable. It should be meaningful to talk about the cross section of a process.

The individual components of a process are, technically, processes themselves, but they may have unphysical cross sections which have to be added for a physical result. Process components may be exclusive tree-level elementary processes, dipole subtraction term, loop corrections, etc.

The beam and structure function setup is common to all process components. Thus, there is only one instance of this part.

The process may be a scattering process or a decay process. In the latter case, there are no structure functions, and the beam setup consists of a single particle. Otherwise, the two classes are treated on the same footing.

Once a sampling point has been chosen, a process determines a set of partons with a correlated density matrix of quantum numbers. In general, each sampling point will generate, for each process component, one or more distinct parton configurations. This is the `computed` state. The computed state is the subject of the multi-channel integration algorithm.

For NLO computations, it is necessary to project the computed states onto another set of parton configurations (e.g., by recombining certain pairs). This is the `observed` state. When computing partonic observables, the information is taken from the observed state.

For the purpose of event generation, we will later select one parton configuration from the observed state and collapse the correlated quantum state. This configuration is then dressed by applying parton shower, decays and hadronization. The decay chain, in particular, combines a scattering process with possible subsequent decay processes on the parton level, which are full-fledged process objects themselves.

### 28.3.1 The Process Object

A process object is the workspace for creating process instances for event generation. After initialization, its contents are filled by integration passes which shape the integration grids and compute cross sections. Processes are set up initially from user-level configuration data. After calculating integrals and thus developing integration grid data, the program may use a process object or a copy of it for the purpose of generating events.

The process object consists of several subobjects with their specific purposes. The corresponding types are defined below. (Technically, the subobject type definitions have to come before the process type definition, but with NOWEB magic we reverse this order here.)

The `type` determines whether we are considering a decay or a scattering process.

The `meta` object describes the process and its environment. All contents become fixed when the object is initialized.

The `config` object holds physical and technical configuration data that have been obtained during process initialization, and which are common to all process components.

The individual process components are configured in the `component` objects. These objects contain more configuration parameters and workspace, as needed for the specific process variant.

The `term` objects describe parton configurations which are technically used as phase-space points. Each process component may split into several terms with distinct kinematics and particle content. Furthermore, each term may project on a different physical state, e.g., by particle recombination. The `term` object provides the framework for this projection, for applying cuts, weight, and thus completing the process calculation.

The `beam_config` object describes the incoming particles, either the decay mother or the scattering beams. It also contains the structure-function information.

The `mci_entry` objects configure a MC input parameter set and integrator, each. The number of parameters depends on the process component and on the beam and structure-function setup.

    end associate
    k = k + n_entry(i)
  end do
  process%config%n_terms = n_tot
end subroutine process_setup_terms

```

Initialize the beam setup. This is the trivial version where the incoming state of the matrix element coincides with the initial state of the process. For a scattering process, we need the c.m. energy, all other variables are set to their default values (no polarization, lab frame and c.m. frame coincide, etc.)

We assume that all components consistently describe a scattering process, i.e., two incoming particles.

Note: The current layout of the `beam_data_t` record requires that the flavor for each beam is unique. For processes with multiple flavors in the initial state, one has to set up beams explicitly. This restriction could be removed by extending the code in the `beams` module.

```

⟨Processes: process: TBP⟩+≡

```

```

    end subroutine process_beams_startup_message
```

We complete the kinematics configuration after the beam setup, but before we configure the chain of structure functions. The reason is that we need the

total energy `sqrts` for the kinematics, but the structure-function setup requires the number of channels, which depends on the kinematics configuration. For instance, the kinematics module may return the need for parameterizing an s-channel resonance.

Insert the structure-function configuration data. First allocate the storage, then insert data one by one. The third procedure declares a mapping (of the MC input parameters) for a specific channel and structure-function combination.

We take the number of channels from the corresponding entry in the `config_data` section.

Otherwise, these are simple wrapper routines. The extra level in the call tree may allow for simple addressing of multiple concurrent beam configurations, not implemented currently.

If we do not want structure functions, we simply do not call those procedures.

```

    end subroutine process_set_weight
```

## MD5 sum

The MD5 sum of the process object should reflect the state completely, including integration results. It is used for checking the integrity of event files. This global checksum includes checksums for the various parts. In particular, the MCI object receives a checksum that includes the configuration of all configuration parts relevant for an individual integration. This checksum is used for checking the integrity of integration grids.

We do not need MD5 sums for the process terms, since these are generated from the component definitions.

```
(Processes: process: TBP)+≡
    procedure :: compute_md5sum => process_compute_md5sum

(Processes: procedures)+≡
    subroutine process_compute_md5sum (process)
        class(process_t), intent(inout) :: process
        integer :: i
        call process%config%compute_md5sum ()
        do i = 1, process%config%n_components
            associate (component => process%component(i))
                if (component%active) then
                    call component%compute_md5sum ()
                end if
            end associate
        end do
        call process%beam_config%compute_md5sum ()
        do i = 1, process%config%n_mci
            call process%mci_entry(i)%compute_md5sum &
                (process%config, process%component, process%beam_config)
        end do
    end subroutine process_compute_md5sum
```

### Integration and event generation

The sampler test should just evaluate the squared matrix element `n_calls` times, discarding the results, and return. This can be done before integration, e.g., for timing estimates.

```
(Processes: process: TBP)+≡
    procedure :: sampler_test => process_sampler_test

(Processes: procedures)+≡
    subroutine process_sampler_test (process, instance, i_mci, n_calls)
        class(process_t), intent(inout) :: process
        type(process_instance_t), intent(inout), target :: instance
        integer, intent(in) :: i_mci
        integer, intent(in) :: n_calls
        call process%mci_entry(i_mci)%sampler_test (instance, n_calls)
    end subroutine process_sampler_test
```

Integrate the process, using a previously initialized process instance. We select one of the available MCI integrators by its index `i_mci` and thus integrate over (structure functions and) phase space for the associated (group of) process component(s).

The finalizer should be called after all integration passes have been completed. It will, for instance, write a summary of the integration results.

`integrate_dummy` does a “dummy” integration in the sense that nothing is done but just empty integration results appended.

```
(Processes: process: TBP)+≡
    procedure :: integrate => process_integrate
    procedure :: final_integration => process_final_integration
```

```

procedure :: integrate_dummy => process_integrate_dummy
⟨Processes: procedures⟩+≡

        call process%mci_entry(i_mci)%prepare_simulation ()
    end subroutine process_prepare_simulation

```

Generate a weighted event. We select one of the available MCI integrators by its index `i_mci` and thus generate an event for the associated (group of) process component(s). The arguments exactly correspond to the initializer and finalizer above.

The resulting event is stored in the `process_instance` object, which also holds the workspace of the integrator.

Note: The `process` object is declared `intent(inout)` because it contains the random-number state, which changes for each event. Otherwise, all volatile data are inside the `instance` object.

```

⟨Processes: process: TBP⟩+≡
    procedure :: generate_weighted_event => process_generate_weighted_event
    procedure :: generate_unweighted_event => process_generate_unweighted_event
